From: b_weeber@...
Topic: 25504 Message: 25540

Hello Stan

If you think about a battery powered receiver, you would probably like the circuit diagram on Bob Weaver's website. Have a look on the last circuit diagram three quarters down:
Three Tube Superheterodyne Receiver Part 1
http://electronbunker.ca/eb/ThreeTubeSuper1.html

http://electronbunker.ca/eb/ThreeTubeSuper1.html

Three Tube Superheterodyne Receiver Part 1
http://electronbunker.ca/eb/ThreeTubeSuper1.html A couple of years ago, I acquired a collection of vintage 1930s era vacuum tubes which were designed to be operated from a battery supply. Some had 1.4 volt...

View on electronbunker.ca http://electronbunker.ca/eb/ThreeTubeSuper1.html
Preview by Yahoo

The three tubes could be replaced by miniature types like:
V1: 1R5, 1AC6 or 1AB6
V2: 1T4, 1L4 or 1AJ4
V3: 1S4, 3S4, 3V4, 3Q4 or 3C4

So turn your parts box upside down and check, if you find something useful.

best regards,
Bernd

Hi Don
I tried to phone you over the last couple of weeks. I keep bumping into your posts/website/emails as I have been juiced about regens lately. I live 20 km south of Peterborough, and am delighted that you are in the RF nieghborhood. I have found that my ultrasonic parts cleaner did a great job on a scuzzy var-cap/ Peter VE3GYY

---In regenrx@yahoogroups.com, <dulmagedon@...> wrote :

I built the regen from the 1943 handbook but did it breadboard and on the other half of the breadboard (I cut it in two) I built the 6l6 breadboard transmitter. Very happy with both. They work very well. I also have started the Simple superhet three tube project from the ARRL book but updated the tube choice to minature tubes. On the regen mentioned at the top I subbed a 6sl7 for the original tube because I had several of them. Here it is just before I finished the receiver and put them both on the air. I was using them again today and I still enjoy this vintage station a lot. I use a Nostalgia 60 watt light bulb over the operating table to help make the mood period correct.

Hi Peter! Well you are not very far away! I have friends in Keene (Vilneff Auto Repair) and Hastings (Larry the bricklayer) as well as family in Peterborough by same last name. I am home today all day. But email also works as does Ham radio. I am good AM (40M and 80M) or (SSB 80M 40m 20m) and of course CW. I have been testing a mag loop antenna on 7290khz this morning using my Hb AM transceiver. Its Receiver is basically the powerhouse regen from the 1970s with mods to suit me. Last evening I was on 80m with my 6l6 transmitter (3542 crystal) and my 6sl7 regen as in the breadboard photos.
Hope to hear from you!

I'm not as particular about component values as others, especially with tuning circuits and power supplies. I use whatever I have on hand and try to adapt the rest of the circuit. That may be why success is so illusive, but I can't see specifying components and values that are unobtainable. Coils are fitted to whatever band I want by resonating them with a known capacitor (with a scope & sig gen) and using the resultant frequency to calculate the inductance of the coil. The physical dimensions and wire of the coil are relatively unimportant. Physical layout of the chassis seems to have more effect on performance. I build my sets just for the fun of making something work. I don't expect Collins performance with a handful of tubes & components, and a skimpy electronics education. Failure has been good to me.

Leonard

Its really nice to examine details in your projects.... especially after researching the old sources .....
and the majority of the parts are obtainable.... some more elusive.

when you say:
Coils are fitted to whatever band I want by resonating them with a known capacitor (with a scope & sig gen) and using the resultant frequency to calculate the inductance of the coil.

Is there any great web description of that design process?... for a neophyte like me.

Rob, There is a site somewhere that shows the process but I can't think of it right now. However, the method I use is shown here.

Adjust the sig gen frequency for max indication, then calculate the inductance, ie;

L=1/(((6.28*freq)^2)*Cap)

I entered the equation into a spreadsheet to do the calculation.

Hi Rob,

If you don't a have a scope that covers the expected frequency range you can use an RF probe (an AM detector) into a VTVM, FETVM, or - less desirable - a DVM (part of a DMM - digital multimeter). The motion of the needle in the VTVM or FETVM is a valuable part of the "user interface" in that role.

Just sweep the signal generator through the frequency range connected across (or through) the resonant circuit and find the frequency where it peaks (or dips). The specified voltmeters will show you. In this case, if you are using a scope it is serving as a voltmeter and is just as nice as the Voltmeters.

That's about as clear as I can make it. The principles are covered in *all* of the radio handbooks.

Bill, I think you're dead on. My command of English is not great, and even worse with any other language. I should mention that the two 2pF caps are there to keep the capacitance of the cables and test equipment from adding to the resonant circuit. they give a sharper indication on the scope/VTVM and reduce the posibility of "second dipping." I'm not a computer geek but occassionally I find something I can do on them that saves me a lot of tedious scribbling.

Leonard

Hi Rob,

Leonard and I both sent you information that essentially agrees and addresses your question. Leonard's comments triggered memory of another, related approach. The use of a grid-dip meter (or gate-dip meter). Google should be your friend.

The question now is whether our replies were of any help to you. So Rob..did you get the information you needed?

25550. Finding resonant frequency of a L/C circuit

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-02 16:33:21 UTC
From: willard561@...
Topic: 25550 Message: 25550

I think a lot of you are missing a easy way of finding the resonant frequency of a L/C circuit, that is to use a Grid Dip/Fet dip meter. They're an easy project to build and very useful.
Bill Higdon

25551. Re: [regenrx] Finding resonant frequency of a L/C circuit

Topic: 25550 Message: 25551

I have a GDO and an FETDO that I use for quick checks, but neither is as sensative as the SG/Scope method. Also, neither of my dippers go much below 2MHz. I alway have a counter on the sig gen because I don't trust the acuracy of its dial. My inductance meter doesn't read reliably below 1mH and is more useful for power supply chokes..All of my test equipment is marginal at best.

25553. Re: [regenrx] Re: Band Switching Regen for 40/80 the MATH

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-03 01:07:12 UTC
From: Rob
Topic: 25513 Message: 25553
Attachments: 1 described; binary payloads are missing from this source WARC

I put the test circuit image here for discussion:
http://www.learnmorsecode.com/help/regen/resonantcircuit.jpg
if the attachment image was lost.

So lets say I wanted to make a tank circuit for AM radio reception...
540Kc to 1600kHZ.....
and just for giggles lets pick 1,000kHz to plug into the formula.
Keeping in mind that I'm not looking for the whole band now... I am just
proofing the math
and revisiting algebra.

the formula in the image is:
L=1/(((6.28*freq)^2)*Cap)

I'm going to assume that 6.28 was Pi times 2.

Using the 100pF capacitor ... I think that I'm supposed to
use .000000001 for Cap.
that is point then 8 zeros in front of the ONE.

For the frequency of 1,000kHz.... that is actually 1,000,000 Hz.

So the formula with fat numbers looks more like
L=1/(((6.28*1,000,000)^2)*.000000001)

so first thing is to multiply 6.28 times 1,000,000 which equals 6,280,000
and then it shows ^2 which really means 6,280,000 squared... equals:
3.94384x10-13

then multiply by .000000001 equals 39,438.4
and then the final step 1 divided by that 39,438.4
equals .000025355

Did I get that right?
and what is that .... micro henries?
is that a 2.5 microhenries....
or is that 25 milihenries?

I have more questions but I'll wait until anyone confirms I got the math
right
and can tell me what unit the result is in.

Topic: 25513 Message: 25555

oops..... 9 zeros... not 8 zeros....
sorry.... I have a vision problem......
result is .000253 or 253 uH (microhenries)

OOOKKKKKKkkkkkkkkk.....

so lets say I wind a coil and it measures 253uH on my Proskit LCR Meter MT-5210 inductance meter.....
at that point I am assuming I have the correct inductance to make a resonant tank circuit for radio reception of 1Mhz.

So for 40 meter CW reception on 7.110 Mhz (its a PIXIE freq for newbies) ..... I get L=.00000501.... or 5 uH

Is that all there is to it?.... use a 5uH coil with a 100pF cap and expect to hear 7.110 on the J310-2N3904 circuit?

I made a variable inductor a while ago:
http://www.learnmorsecode.com/help/rfcoilandferrite.html

=======!=====!======!======!=======!==========
The numbers are right but I think the cap should be .0000000001.(9 "0's before the 1) That would come out .00025355, or 253 uH (microhenries)

I'm using an $11 SHARP EL-531X calculator... with a magnifying
glass...damn small print on the buttons.....
finding too many zeros like 9 leading zeros ends that game real quick.....
resorted to learning about the Exp key......
entering frequency of 1Mhz as 1 EXP 6
and capacitance off 100pF as 1 EXP -10
and then multiply the final answer by 1 EXP 6
to get those 253 and 5 microhenries.

As a retired computer programmer I must say I never once pushed an EXP
button in 20 years
for anything.
But this EXP definitely makes very short work of this formula.

You got it, except stray wire capacitance will skew your results slightly. It's always best the have a way to vary the cap or inductance.

Leonard

oops..... 9 zeros... not 8 zeros....
sorry.... I have a vision problem......
result is .000253 or 253 uH (microhenries)

OOOKKKKKKkkkkkkkkk.....

so lets say I wind a coil and it measures 253uH on my Proskit LCR Meter MT-5210 inductance meter.....
at that point I am assuming I have the correct inductance to make a resonant tank circuit for radio reception of 1Mhz.

So for 40 meter CW reception on 7.110 Mhz (its a PIXIE freq for newbies) ..... I get L=.00000501.... or 5 uH

Is that all there is to it?.... use a 5uH coil with a 100pF cap and expect to hear 7.110 on the J310-2N3904 circuit?

I made a variable inductor a while ago:
http://www.learnmorsecode.com/help/rfcoilandferrite.html

=======!=====!======!======!=======!==============
The numbers are right but I think the cap should be .0000000001.(9 "0's
before the 1) That would come out .00025355, or 253 uH (microhenries)
Leonard

540Kc to 1600kHZ.....
and just for giggles lets pick 1,000kHz to plug into the formula.
Keeping in mind that I'm not looking for the whole band now... I am just proofing the math

and revisiting algebra.

the formula in the image is:
L=1/(((6.28*freq)^2)*Cap)

I'm going to assume that 6.28 was Pi times 2.

Using the 100pF capacitor ... I think that I'm supposed to
use .000000001 for Cap.
that is point then 8 zeros in front of the ONE.

For the frequency of 1,000kHz.... that is actually 1,000,000 Hz.

So the formula with fat numbers looks more like
L=1/(((6.28*1,000,000)^2)*.000000001)

so first thing is to multiply 6.28 times 1,000,000 which equals 6,280,000
and then it shows ^2 which really means 6,280,000 squared... equals:
3.94384x10-13

then multiply by .000000001 equals 39,438.4
and then the final step 1 divided by that 39,438.4
equals .000025355

Did I get that right?
and what is that .... micro henries?
is that a 2.5 microhenries....
or is that 25 milihenries?

I have more questions but I'll wait until anyone confirms I got the math

Don't feel all alone, Rob. I've been on my second retirement for the last 8 yrs and I'm starting to forget my math. I frequently have to redevelop my equations before I can use them. That's why I started putting the formulas in my spreadsheet to reduce the errors I was getting with misplaced decimal pts, etc.

25559. Tank Circuit Calculations - L, C & F

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-03 07:15:35 UTC
From: les.au49@...
Topic: 25559 Message: 25559

G'day all:

The ARRL handbook from "those days" gave a short formula relating inductance (microhenries), capacitance (pico-Farad) and Frequency (MHz).

L * C equals 25330.29/(F * F)

Example #1. If you want to build a circuit that tunes 3.56 MHz then the product of LC must be 25330.29/(3.56 * 3.56) = 1998.66

This is more accurate than YOU need, but you can check the accuracy of your calculation from the example. If you have a 20uH coil, your capacitor must be 99.9pF.

Example #2. Suppose you have a "precision" capacitor, 100pF in value. Your "prize" coil, wound on a ceramic former (and very nice) resonates at 3.60MHz. What is the value of this "nice" coil?
Answer: L equals 25330.3/(3.60 * 3.60 * 100) = 19.54 micro-Henries

Example #3. Known "L", unknown "C".
The coil and capacitor resonate at 2.1MHz
The coil inductance is 9.5uH
What value is the capacitor.
C equals 25330.3/(Freq * Freq * L) = 25330.3/(2.1 * 2.1 * 9.5) = 604pF

Example #4. I have a 15uH coil and a 150pF capacitor.
What is the resonant frequency of the tank circuit?

Freq equals sqrt (25330.3/LC) = sqrt(25330.3/(15*150)MHz = sqrt(11.26) = 3.355MHz

Some words of explanation:
A "tank" circuit is a parallel combination of coil and capacitor - as you see connected to the grid of many regen detectors.
I understand it is called a "tank" circuit because the electricity "sloshes" up an down in the capacitor in the same way water will slosh around when a water "tank" is disturbed. (If you have a better understanding of why the word "tank" is used, I'll be pleased to hear it!

The "magic" number 25330.29 is simply 1,000,000/(4 * pi * pi). Try it!
The "long" formual is LC = 1,000,000/(4 * pi * pi * freq * freq), but 25330.29/(F*F) is more convenient, c'est nes pas?

I started a new thread, with a new topic, because the previous thread (now discussing L,C and Frequency) started with a completely different subject. Now the subject heading and the content match again.

This is my first posting for the new year.

25560. Re: [regenrx] Tank Circuit Calculations - L, C & F

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-03 07:57:40 UTC
From: Bill Houghton
Topic: 25559 Message: 25560

I suspect its called a tank circuit because the energy is stored. In capacitors energy is stored in an electric field. In inductors energy is stored in a magnetic field. At one point all of the energy will be stored in the capacitor's electric field. As the capacitor discharges the energy stored in its electric field will be stored in the inductor's magnetic field. At another point in time all of the energy will be stored in the inductor's magnetic field. As the magnetic field collapses, it's energy will be stored in the capacitor's electric field. This results in a recirculating current in the tank circuit. If there were no system losses, the current in the tank circuit would continue forever.
Where do those formulas come from? The come from the idea that at the frequency of resonance, the inductive and capacitance reactances are equal, and thus,
2 pi fL = 1/(2 pi fC)

Subject: [regenrx] Tank Circuit Calculations - L, C & F

G'day all:

The ARRL handbook from "those days" gave a short formula relating inductance (microhenries), capacitance (pico-Farad) and Frequency (MHz).

L * C equals 25330.29/(F * F)

Example #1. If you want to build a circuit that tunes 3.56 MHz then the product of LC must be 25330.29/(3.56 * 3.56) = 1998.66

This is more accurate than YOU need, but you can check the accuracy of your calculation from the example. If you have a 20uH coil, your capacitor must be 99.9pF.

Example #2. Suppose you have a "precision" capacitor, 100pF in value. Your "prize" coil, wound on a ceramic former (and very nice) resonates at 3.60MHz. What is the value of this "nice" coil?
Answer: L equals 25330.3/(3.60 * 3.60 * 100) = 19.54 micro-Henries

Example #3. Known "L", unknown "C".
The coil and capacitor resonate at 2.1MHz
The coil inductance is 9.5uH
What value is the capacitor.
C equals 25330.3/(Freq * Freq * L) = 25330.3/(2.1 * 2.1 * 9.5) = 604pF

Example #4. I have a 15uH coil and a 150pF capacitor.
What is the resonant frequency of the tank circuit?

Freq equals sqrt (25330.3/LC) = sqrt(25330.3/(15*150)MHz = sqrt(11.26) = 3.355MHz

Some words of explanation:
A "tank" circuit is a parallel combination of coil and capacitor - as you see connected to the grid of many regen detectors.
I understand it is called a "tank" circuit because the electricity "sloshes" up an down in the capacitor in the same way water will slosh around when a water "tank" is disturbed.
(If you have a better understanding of why the word "tank" is used, I'll be pleased to hear it!

The "magic" number 25330.29 is simply 1,000,000/(4 * pi * pi). Try it!
The "long" formual is LC = 1,000,000/(4 * pi * pi *! freq * freq), but 25330.29/(F*F) is more convenient, c'est nes pas?

I started a new thread, with a new topic, because the previous thread (now discussing L,C and Frequency) started with a completely different subject. Now the subject heading and the content match again.

This is my first posting for the new year.

Happy New Year to the group,
This is my favorite subject and I just love this new formula and insight. I like the one with .159/sq rt of LC
I do have another tank story, I read a few days ago is that since the damped wave eventually tanks out it is a tank circuit.

If you bias your LC circuit to a negative value, then you have an under-ground tank circuit.

This is one good online calculator I found, in that it works with "real" units of your choice (don't have to use exponents or count zeroes ;-)
http://www.1728.org/resfreq.htm

You can solve for any unknown parameter (L, C or freq)

Regards,
Mark KB9VKE

Topic: 25559 Message: 25567

As nice as the online calculator is at http://www.1728.org/resfreq.htm
I REALLY appreciate the detailed explanation:

Printed ..... saved... on READ ONLY MEDIA then snapshot taken and posted
forever where I KNOW
I will not lose it online at
http://www.learnmorsecode.com/help/regen/tankcalc.jpg

THANK YOU

++
L * C equals 25330.29/(F * F) OR USE
L=1/(((6.28*freq)^2)*Cap)
L is uH C is pF F is Mhz L is
H freq is hertz Cap is F (lots of zeros so use EXP -10 for 100pF)

Example #1.
If you want to build a circuit that tunes 3.56 MHz then the product of
LC must be 25330.29/(3.56 * 3.56) = 1998.66

This is more accurate than YOU need, but you can check the accuracy of
your calculation from the example.
If you have a 20uH coil, your capacitor must be 99.9pF.

Example #2. Suppose you have a "precision" capacitor, 100pF in value.
"prize" coil, wound on a ceramic former resonates at 3.60MHz. What is
the value of this "nice" coil?
Answer: L equals 25330.3/(3.60 * 3.60 * 100) = 19.54 micro-Henries

Example #3. Known "L", unknown "C".
The coil and capacitor resonate at 2.1MHz The coil inductance is
9.5uH What value is the capacitor.
C equals 25330.3/(Freq * Freq * L) = 25330.3/(2.1 * 2.1 * 9.5) =
604pF

Example #4. I have a 15uH coil and a 150pF capacitor. What is the
resonant frequency of the tank circuit?
Freq equals sqrt (25330.3/LC) = sqrt(25330.3/(15*150)MHz = sqrt(11.26) =
3.355MHz

++

I have never read an understandable explanation of how this works. Yes, I know how the circuit is configured, and that it DOES work, just not the how and why of it.

I am messing about with the Knight Kit Star Roamer general coverage receiver that my Dad helped my older brother build when I was really young. It uses regeneration in the IF via the subject method. This is done to increase sensitivity, as a Q multiplier, and in oself oscillating mode to provide a beat note for CW reception. The action of the circuit seems to be VERY sensitive to adjustment of the IF cans.

In particular, it would be nice to know if the regeneration is more dependant on the input or the output IF transformer for this stage. (The one connected to the plate, or to the control grid, in other words.)

Years ago I was messing about with this trying to get it to work, and managed to destroy one of the IF cans, even though I did have a proper plastic hex tool.

I was finally able to obtain a NOS set of IF cans that fit correctly. (ebay) These are working, more or less. (I am able to recieve strong local stations, and 10MHz WWV at approximatly the correct dial settings.)

Before I try to improve the alignment, I want a good understanding of the circuit, so I can "get in, and get out" and hopefully minimize the chance of ruining another IF transformer. They are becoming really hard to replace.

Here is a detail of the schematic showing the IF. R4 is the regeneration control, labeled "Sens."

Hi Kevin,

It has been quite a few decades since I used a Star Roamer. The BFO function wasn't all that great BUT it did work..mostly. Looking over the schematic I think the plate circuit is the most likely suspect since the suppressor grid is the element being changed by the sensitity control and that removes the 'shielding between plate and screen. Make sure all the other IF slugs are peaked. The plate slug might be used to change the frequency of the "BFO" and it will more useful tuned to one side of the peak for CW. But you are up the creek for changing Sidebands while listening to SSB. With all four slugs set at peak the BFO will be in the center of the passband and you have the audio image for all signals depending on how you tune.

It's not useless but you will have to be a *radio operator* to get satisfaction. If you do get the hang of it you'll be batter off AND you'll appreciate better designs. Enjoy your Star Roamer.

Hue,

Watch out if you use the toroids for your tank circuit! Its hard to adjust your tickler windings because one pass through the toroid is often too much and dont know how you could get less than one turn feedback.

People smoking around me used to not bother me, but lately, as soon as someone lights up I find a reason to run away. That stuff sure permeates everything.

Doug

I have one S-38C with that wire wraped around the plate pin. The bfo oscillates, but the frequency is about 20 kHz away from 455kHz / if passband. Once a station beats with the bfo, the signal is so far away, the loudness is already very low. In the same time the disturbing qrm is still peaking, which causes a bad s/n ratio.

Throwing the IF stage with its 2 LC circuits at 455 kHz shouldn't change the frequency 20 kHz unless maybe the current thru the tube radically changes during oscillation. The bias voltages are all correct ?

Hi,

Many transistors are almost (virtually) free. The energy to run them is also quite modest.

Within a few months of smoking my last cigarette (decades ago) I bought another new car (a pickup truck actually). In mid winter, windows all rolled up, 70 mph on the expressway a smoker in his car passed me. I was amazed that I could smell his cigarette smoke through two sets of closed windows with ~70 mph intervening winds. That gunk *eats* electronic parts, too. Radios and accordions that smell of tobacco smoke are not good buys.

Interelectrode capacitance. The 5k pot is in series with the 2.2k resistor and varying the pot increases or decreases the amplitude of the current flow which is probably close to being in-phase.

** maybe the current thru the tube radically changes during oscillation

The coupling is very loose and the amplitude is not very high. My voltages are normal and the receiver works well with am stations. When turning on the bfo, the bias is not changing, but the coupling between grid and plate increases by ~1pF. Because the tube has a amplification, the Miller effect increases the capacity to a multiple of this 1pF and IMO causes the frequency deviation.

The S-38A has one extra tube for the bfo. People, who own one, mention, that this combination works well. Then Hallicrafters tried to save the tube, which caused the B and C type, to get worse. They changed the circuit on the following models again, which for me is an evidence, that former owners have been complaining.

Best regards,
Bernd

I think your explanation seems the correct one.
If it is, the only way to counteract that would have been to use a much higher C:L ratio in the IF tuned circuit, but that would have lowered the
output impedance and lessened the sensitivity. Still, maybe that would work; i'm just speculating.

You are saying the IF frequency change is only noticed when oscillating? I understand it would be hard to observe when not oscillating, only approaching.

For the circuit to oscillate, the plate circuit has to be seen as capacitive reactance compared to the input tuned circuit, to complete the
correct phase shift for the feedback. That means the plate circuit has to be at a resonant frequency higher than the oscillating frequency.
Sorry, i'm just thinking about this interesting problem. It's obvious the circuit designers didn't spend too much time on it.
I'm wondering if some kind of stagger-tuning the IF circuits would minimize this.
-Hue

Hello Hue

** it would be hard to observe when not oscillating
The if has been adjusted before with help af a wobbulator. The passband looked nice and narrow. After recognizing the bfo frequency deviation, i tried to find a compromise setup. It was impossible, to tune the bfo frequency close to the 455 kHz and in the same time keep a usable if filter curve.

Hi,

I think over the years everybody has agreed the *fake* BFO is not not nearly as good as a *real* BFO but a fake BFO is much better than *no* BFO at all. Every decision is a compromise most of the time. With radios like the Star Roamer you get the radio cheaper. You are required to live with the consequences of that decision. My own memories of using the Star Roamer are good ones in spite of it's sometimes annoying limitations. Tune your IF as stated in the manual (the wobbulator is a goof choice) and then enjoy it for what it is.

I wonder if users of the Star Roamer and Hallicrafters SX-140 noticed
this same effect, IF frequency shift, when in the BFO mode.
No one has reported it. It may be just that no one really noticed it,
among the other other characterisitics such as fussiness, lack
of sensitivity, etc., generally not stellar performance.

Hi,

I missed something along the way about the BFO shifting frequency from it's non-oscillating state to it's oscillating state. Well yes. From zero Hertz to something near 455 kHz. Obviously something else must have been meant. If you know that it is oscillating to one side of the IF passband that is ideal! Absolutely perfect! Well.. maybe not that good but better than oscillating in the center (+/- zero Hz). You almost always want the BFO down one passband slope or the other.

But what about the other sideband? You want to receive lsb and usb. As long as the bfo can't be tuned, it should oscillate somewhere inside of the passband. Eventually a Colpitts-Circuit could have solved the problem.

Hi,

Did anybody mention this is a cheap way to get a BFO and does have some disadvantages? There..I just mentioned it - again. An additional stage would cost more money. Read some of the rants that have appeared on usenet and the mail reflectors over *pennies*.

On the ham bands we use LSB at 7 MHz and lower frequency bands. We use USB for 14 MHz and higher bands. 10 MHZ is CW or digital and sideband can be finagled for digital and matters not on CW. So it will actually work if the VFO works above the incoming signal on 160 through 40 meters, and below the incoming signal on 14 MHZ and higher. Or the other way 'round'. The side bands trade places. If I still had a Star Roamer I would measure the *fake* BFO signal - again. I'll leave that to somebody else. Somebody who actually has one today.

The *fake* BFO is where it is. Best of luck and enjoy the radio for what it is.

Bill, i think you kinda maybe missed some of the messages on this topic.
Berndt says when the S-38 goes into oscillation,
the frequency of oscillation is offset from the IF center by 20 kHz. I
think Berndt is right when he says a better type
of regenerative IF stage would have used a Colpitts feedback stage.
Instead of TPTG oscillator, which is what the IF
becomes when the suppressor becomes disabled. A 20 kHz offset certainly
doesn't make the best use of the IF LC's
tuned to 455 kHz.
Almost makes me wish i had one of the radios using this scheme, so i
could try to improve it. Almost. Too many
projects as it is.

Hi Hue,

Thanks. Yes I did miss some of the messages including that somebody measured the "BFO" offset. 20 kc is just too much. I also had thought the thread was about the Star Roamers. I had and used one of those. I don't even have the notes any more but for the individual radio I had the offset was not unreasonable and worked out to be correct for the different ham bands. I know nothing of S-38s or even *other* Star Roamers for that matter.

It would be fun to play with one again but as you said..to many other things have priority. I'm working on homebrew SDR hardware. The part that lives outside the computer. Vacuum tube SDR anyone? As part of that exploration I have fed computer sound card based DSP systems with the output from regens. Not so very far off topic and very encouraging.

Ten Tec once offered regen receiver kits, but then that came to an end.
I just read a letter to the amateur repairs list from the owner of
Dishtronix
http://www.dishtronix.com/about.html
which frankly, i had never heard of before. The firm has apparently
downsized
its employee count but will stay in Tennessee U.S.A., however it sounds
like the
new products envisioned will be even more upscale and higher tech -
definitely
no beginner kits anymore.

Due to a posting on one of the other mail reflectors I ran across the following site that has a LOT of vintage radio manuals and other general electronics information. I just completed downloading all of it and adding it to my "Electronics Information" folder with is about 125GB in size. . .

The site is from Argentina and is in Spanish, but much of the material is in English.

Rare to have a major ham equipment supplier die and come back to life as history is not good in this regard. Most likely if they do come back it will he with very different products.

Some nice regen kits have geen recently offered by 4stateqrp and qrpkits.com.

Another trend is taking assembled modules, something like a dongle or dds circuit board and crafting a project from it. Our demise of opportunity is exagerated we just have to adapt as needed.

It is difficult to know what might have happened.
An email address can be lifted from the owner or from
the address book of someone else. Spammers can
either physically use the "victim's" computer to unseen spew spam
far and wide or simply mimic the email address.

If others have likewise received "fake" emails, that would be a clue.

It is always a good idea to change passwords from time to time,
in this instance for Y'hoo and for the email client (program) used.

25606. 6AU6 Audio Output stage - and more

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-10 01:59:53 UTC
From: Hubert Miller
Topic: 25606 Message: 25606

I found the article i mentioned earlier about using a voltage-amplifier pentode 6AU6 for audio output in equipment where low audio power, ca. 300 mW, is all that's needed. The circuit boasts low plate power and filament power consumption.

The article is at
http://www.americanradiohistory.com/Archive-Radio-News/50s/Radio-News-1955-05.pdf

page 124.

Also very interesting in this same date are:
"A Most Unusual Oscillator" p. 52 - oscillator uses only electrons emitted from filament to operate. Not what you're thinking, that it's a filamentary
type tube with the filament voltage as B+. Illustrated is are two oscillators with no connection between the filament circuit and the rest of the circuit.
Here's an interesting statement: apparently the effect is sensitive enough that "The Seebeck effect (thermoelectric effect) from a soldered joint can
stop it".

Also: "Germanium Diode Oscillator" p. 55, discusses cooling of the diode too.
Interesting stuff, i think.

Hello Hue,

Many transistor radios put out 250mW to the speaker.
For a long time I wondered why earlier tube-type receivers put out 1000mW (as a minimum).

Fashion, I guess.
Rather like the idea of running 'tube' receivers with 250V on the B+ line when 120 or 150V works nicely.

Les

BTW - the Radio Controlled boat on the front cover of the Radio News magazine is "heaps cool". I'll bet the woman who is controlling it is "heaps happy" too.

Some of the National receivers had 2 6V6 in the audio section. I never really understood that for a supposedly communications type radio.
If you wanted to have a speaker outside and entertain a party or picnic, maybe.
Maybe it was 'bragging rights', like "Our new Model-X car has a 12-cylinder engine! Not everyone will be able to afford this!"

On the other end of the spectrum, to the more practical, i note that some of the WW2 German receivers used the same tube all the way thru, in every socket. One example is the Fu.H.E. series. With output to a couple headphones, more than enough.

I bought a VLF converter kit and it came a few days ago. No instructions no pictures no hint where to get them. Just a bag of parts. Eventually I found a picture on the internet and some instructions. Parts go apparently on the opposite side of the board as I normally used if the picture is right. Kinda of discouraging. Hope it works. Haven't started on it yet. Not in the mood. Should have just built my own. Built a lot of kits in my youth. Test equipment mostly. Some Heathkit some Eico. Liked Eico the best. Did my first at 9 years old. A Eico VTVM. Dad bought it and asked if I wanted to do it. We had it for years. Why one would ship a kit with no instructions is beyond me. Must be an ethnic thing. I sure don't comprehend the concept. I probably have all the same parts anyway. Tis the plan of attack that makes it work. So will I ever order another one. Probably not now. Instructions can be the difference between fun and frustration. At my present age I am not looking for more frustrations. Kit makers should be aware of that.

The Heathkit GR-64 & GR-91 used the same BFO along with some of the Lafayette short wave receivers.

German Military Comms - WWII

Hello Hue, I'm posting a new topic as a result of your comment that some German receivers used a single 'tube' in a receiver. I have an article - CQ August 1980 - that makes that point for the "Tornister b". It's a 4 "tube" 'straight' regen set. The author (Dick Rollema) wrote that "although the design is over 40 years old [writing in 1980] the set still performs remarkably. As is to be expected the set is at it's best on c.w. [...] but also on the long and medium wave broadcast band many more stations were copied than on a modern superhet."

After that he comments on the performance of this set in the 40m band. "Even in Europe's extremely crowded 40m band, with it's many intruding strong broadcast stations, amateur CW signals can be easily copied at night, a test that many modern superhets fail."

All that in a back-pack regen. set with 4 tubes - all the same type!

I thought I should post those observations here!

Les

I have been saying that for years about regens in general. You can have 80 transistors and a couple of ICs superhet or a couple of tubes in a well designed regen. The number of stations found will in most cases go to the regen. I don't find it difficult to use one despite all the palaber about poor selectivity etc. And Deutsche elecktroniks were always very good ever since Hertz drew his first spark. Very hard to buy a Torn or VolksEmphanger these days. Big bucks, so I had to make my own. 4 tube transceiver complete with Deutsche labling.

Maybe someone should have a frequency stability vs. weight graph. I have a lot of those WWII German military receivers and they not only were built like a tank, they also weighed close to one. Superb craftsmanship. The small Volksemphanger is a different class altogether, and, as a receiver is really poor. That was also by design. 73 – Mike

Speaking of built like a tank, As a young teenager before I could drive (legally;>) I had bought a pair of No 11 Wireless Sets.; One I was able to get running. They were built before the No 19 but used in the same application. Where the No 19 s a kinda light weight tinny set they were built tough as nails. All the bypass caps were bolted in on the ground side and the brackets were over 1\8 inch think. Vernier was gear reduction and I think you could have dropped one of the Empire State building and it would have survived. My Dad's Lab was doing a final test of a set of HF radios for one of the oil companies and they wanted to test against another HF set. Since my good No 11 was made by their company (PYE) during the war he wanted me to set it up in the lab so they could use it to compare. He told me years later (which speaks to what Mike just said) It was far more stable a radio then the new set would ever hope to be. In fact he said ROCK SOLID. Unfortunately when I discovered cars and girls I forgot about radios for awhile and left them somewhere in one of my many moves. I have never had the oppourtunity to replace them and have only seen one other since (Communications Museum at CFB Kingston.) Speaking of German radios . Rhine River cruises often stop overnight in Speyer Germany. People go up town in the morning. If you go the opposite way from the doc they show you there is Speyer Tekniks Museum just a few hundred yards from the dock and they have a large well equipped radio room from that era about centre of the back wall of the museum.

Hi Mike,

I remember seeing a Torn at Kutztown and being *very* impressed. This model had a turret band switch, and one section was warped, causing the band switch to be stuck. I thought "where am I ever gonna get parts for this thing?" so I passed on it. Now I regret it, of course.

If it was one of the ground radios produced possibly with a manufacture date of 1943, and certainly if 1944 or 1945,
the warped turret section was likely a sign of metal swelling, and you made the right decision.
BTW, the battery box for the Torn.E.b. is rarer than the receiver, and the Euro price for a battery box is now about
$800+

Hi Hue,

Yes, that's exactly what it looked like to me -- a warped/swollen "pot metal" casting. But it was only one section, IIRC. So I could have sacrificed that band, I suppose. I know I'll probably never see another one, at least not reasonably priced.

A reminder to everyone - The NOVICE RIG ROUNDUP is coming February 20 - 26.

Time to start checking out your vintage CW gear from the 1950s thru 1970s and make sure it works with your key or bug!

Exchange SKCC numbers along with the usual.

There will be many homebrew tube QRP rigs running just a few watts too!

This event is listed on the SKCC Calender. You can also find complete details at:

http://NoviceRigRoundup.com

It lasts for a whole week of 24-7 fun - see you there!

73 de AF4K, Bry Carling

SKCC number 1879S

Hello Mike,

I've never seen a German receiver - and never, ever seen one of these famous ceramic coil forms used in these sets. Is it true that the "wires" were deposited on the ceramic former by some sort of electrolytic process? How was that done. Since ceramic is an insulator, and can't act as a cathode, I can't understand this process.

I'm curious

Les

I remember some sort of process called "sputtering" that can deposit metal on glass or ceramic but it doesn't use the glass as an electrode. I would have to look it up and learn about it all over again. And then I would probably find out that "sputtering" isn't really the process after all. Can you spell "once upon a time"?

Here is one of these silver coated ceramic coils, it is unused.
Unfortunately it is unknown, to which transmitter/receiver it belonged.
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/silver-coil.jpg
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/silver-coil.jpg

Length of ceramic body: 66mm
Length of coil: 38mm
Diameter: 45mm
Resistance of coil: 0.83 Ohms
Inductivity: ~20µH

It looks like the complete surface has been silver coated, then afterwards they used a machine, to grind a space between the turns. Also the two connection holes are coated from the inside. A wire tap can easily be soldered anywhere on the silver coil

...Hescho also manufactured coils comprising a ceramic former onto which the silver windings were burned. The results exceeded everything known before, as relatively small short-wave oscillator coils with Q-factors exceeding 500 could now be mass-produced. Also the temperature stability figures of these coils were improved to an unprecedented height. Siemens reported coefficients of up to 200 times better than those that could be obtained from the best conventional coils so far.

Sputtering is correct. It is done at modest vacuum (10 microns or so, attainable with mechanical pump) levels. A target is bombarded with ionized gas, which knocks metal off the target. It flies about and sticks to most anything. It is very common in scanning electron microscopy, as the samples must be conductive. If you have ever seen an electron micrograph of a fly eye, or similar, it was first coated with metal by sputtering.

The silver might have also been applied by chemical means. A metallic salt solution (silver chloride) is applied and allowed to dry. Then it is converted to metallic silver by light exposure, or chemical or thermal means, and then the deposit would be treated in a furnace to amalgamate the discreet crystals of silver that are produced.

In any case, only a very thin layer is needed initially...once that is applied, the deposit can be built up to any desired thickness by electroplating.

While chasing info about the question of high stability coils I found an article that dealt with the problem of stability in a different way - freezing the ceramic former and heating the winding wire as the coil was wound. By this mechanism (the author claimed) he got a VFO that was sufficiently stable to allow it to be used on 2 meters.

I can't say anything about that claim (except to say some claims about V.F.O. stability are laughable because they are patently false). I'm interested in the topic of oscillator stability, and the performance of the German sets.

Bernd, I found your photo, and "chased" the source. I ended reading pages written by PA0SE; I found his description of German WWII sets. Some (for example the Tornistor (or Tornister) were T.R.F. Others were superhets. The T.R.F. sets are always presented as workable, quiet, and (in particular) not subject to the problem of cross-modulation in the presence of "nearby" strong signals.

Here: http://www.noding.com/la8ak/12a.htm http://www.noding.com/la8ak/12a.htm

he lists the spec for a superhet, the E52 Kohn, with stability figures of 30Hz. Now THAT is impressive.
The "top" frequency is given as 25MHz.

Here: http://www.noding.com/la8ak/12b.htm http://www.noding.com/la8ak/12b.htm the second page of the article describes the development of coils:

"COILS
As already mentioned in RB65, the firm of Hescho also manufactured coils comprising a ceramic former onto which the silver windings were burned. The results exceeded everything known before, as relatively small short-wave oscillator coils with Q-factors exceeding 500 could now be mass-produced. Also the temperature stability figures of these coils were improved to an unprecedented height. Siemens reported coefficients of up to 200 times better than those that could be obtained from the best conventional coils so far."

I don't understand the word, "burned". A coil with "Q" exceeding 500 - I understand very well!

My interest is in simple superhets - this invariably demands a stable VFO (to receive SSB) and (because the set is "simple") a regenerative detector. This type of set will never perform as well as a modern commercially built superhet, but if one wants to BUILD (as opposed to operate/buy) then a well-built "Jones super" will perform well for reliable 2-way communication. V.F.O. stability and dial mechanism are the "tricky bits".

My "Jones super" will reliably hear S.S.B. on 80m from Tasmania, a distance of about 1200km. Alas, I still lack an adequately calibrated dial. My set uses a x2 FET 'cascode' mixer followed by an infinite "Z" detector. Now I want to try the same style of receiver built using "our" Prof. Coro's formula - using the 6AK5.

That's why I'm interested in German TRF sets from WWII.

Les
PS Thanks Bernd, for the photo. Tres interresant! спасибо!

This is fascinating stuff!

Pre-shaving, I had various heavy German units to play with.
They were dumped in the courtyard at my father's HE college
for anyone to pick over.

Not assumed in working order, they were dismembered for useful parts.
I remember the coil formers with no winding (sic), so they were
dumped. Wail ! But I used many components in my early receivers.

Les, is the circuit of your FET Jones super on the group site?
If not, there is one small voice in the old country who would be
most interested...

Bernd, ist die Schaltung vom E52 'Köln' irgendwo downloadbar ?

Michael

is "simple") a regenerative detector. This type of set will never perform as well as a modern commercially built superhet

That is simply not so. Even modern superhets with 101 transistors, ICs and computerized dinglhorphers or whatever, are relatively deaf compared to a good working regen. They are though easier to operate. In fact can be run by someone with zero relative skill level which a regen cannot and that is probably their biggest advantage. There is currently a move affoot to re-explore some of the simpler designs. And I don't mean in the hobby world either. Just because something is complicated and modern does not mean it is a better performer. Often it just means it is complicated modern and expensive. Just today during the Linc Cundall event I had a golden oppourtunity to compare a modern digital Rx against a 1930s style regen (56/58 tube). I was in QSO and lost my contact in the background noise but had my regen also on freq. I shut off the digital and flipped the B+ on on the regen. There he was beeping away. I was impressed to say the least. Eventually I did lose him anyway as the band was changing but the regen went a lot farther, measurably more then the digital could.

Subject: [regenrx] German Communications from WWII

German Military Comms - WWII

Hello Hue, I'm posting a new topic as a result of your comment that some German receivers used a single 'tube' in a receiver. I have an article - CQ August 1980 - that makes that point for the "Tornister b". It's a 4 "tube" 'straight' regen set. The author (Dick Rollema) wrote that "although the design is over 40 years old [writing in 1980] the set still performs remarkably. As is to be expected the set is at it's best on c.w. [...] but also on the long and medium wave broadcast band many more stations were copied than on a modern superhet."

After that he comments on the performance of this set in the 40m band. "Even in Europe's extremely crowded 40m band, with it's many intruding strong broadcast stations, amateur CW signals can be easily copied at night, a test that many modern superhets fail."

All that in a back-pack regen. set with 4 tubes - all the same type!

I thought I should post those observations here!

Les

Topic: 25613 Message: 25633

Hello Don,

I am interested in the German sets because they represent an effective form of DIY communication. I have a handful of useful gear available here - Kenwood, Yaesu & co - but this represents "buy and call" technology.

I can't make any comment about the performance of (homebrew) regen sets compared with commercial rigs. I haven't made that comparison myself. However, earlier I posted the comment from 73 magazine about the performance of the German Tornistor. The impression I got from the article was that the 40 y.o. "Torn" "worked" on 40m. The problem is that we can't compare that set - made for the military by German industry - with a home-brew set. I'm not looking for competition-winning performance - I believe the measure is "do-able" and "workable". Leonard's sets are a good example of "do-able", and (I must say) following Leonard's "doings" is a lot of fun.

Even though the Torns are basic 4 tube sets only a tradesman in a well equipped workshop (lathe, metal folder, drill press and so on) would try to build such a mechanical marvel as the "Torn". And I think that makes the point very well - a good set has to be built solidly. It seems to me that we home-brewers should concentrate on mechanical construction, more than an7y particular circuit. Our sets may not be be built "like at tank", but they should have a solid chassis, and a tuning mechanism to match.

To conclude: Here (in Australia) 40m is crowded - just as everywhere - so selectivity is an important part of the specification. I've never seen figures for the selectivity of a regen. set. That makes a comparison with other sets - superhets - difficult. Ditto for cross-modulation and noise figure. If you, Don, (or anyone) has figures I'm 100% interested. 100%. Has anyone put a wobbulator near a regen set? I'd like has, or even knows how to do it, do tell me. Until figures arrive, all we can say is that regen. sets work "well enough" to be practical.

Les

Take what you read about German communications equipment with some
healthy skepticism.
The Torn.E.b. for example. It's a 4-tube regn of the 1-v-2 layout using
tubes equivalent to our 1T4.
There is no way to get magic out of that combination no matter how
outstanding the mechanical
engineering.
Speaking of engineering, advanced engineering didn't prove to be the
salvation of the Reich in the
war. In fact there were numerous engineering mistakes. I was just the
other day reading a short
memoir of the North Africa campaign where a U.S. vet described much of
the German mechanical
equipment as junky or flimsy. In wartime weaponry, they actually had too
many different weapons.
The famed Tiger tank was a very expensive production and was produced in
much smaller numbers
than the mass-produced Allied tanks - and particularly the Russian tanks
which were the deadliest
challenge to the panzers. In radios, i noticed that they had too many
different tube series which
were not interchangeable. For example, backpack radios that used 2 volt
tubes and others that
used 2.4 volt tubes. Or a field radio weighing about 55 lbs. for 2 watts
output. They did build what
many call the best communications receiver of the war, the E52 and the
vhf counterpart E53, but
Hallicrafters had a SSB adapter for their SX-28, and HF-DF receivers
with instant direction display,
so the Allies weren't laggards either. There was no magic to German
communications equipment.

@Les
When manufacturing ceramic, for example a cup, the material is heated up a few times after painting and coating and then slowly cooled down. If they used the sputter technology, afterwards it could have been heated up again above the melting point of silver and after some time the silver could intrude into the ceramic, to get a better mechanical stability. Heating up and cooling down very slowly over 24 hours could help to get rid of any tension in the material.

Seems, this is the original patent from 1936:

The original is found in Pat Hawker's "Radio Amateur Techniques".
I built many variations on this circuit, but always used this circuit as a starting point.
I used various "back ends" - discrete transistors, JFET + bipolar transistors, OpAmps, with & without AGC.
The regen control is very smooth - I watched the oscillations increase from a few mV (on my CRO) to 100mV or more. Very predictable, very smooth. It's a good circuit.

Ok fair enough. I don't personally care much about specific figures and tests. I want a set that works. I have three regens that are very practical to use. The 56/58 set is the best as it regularly outperforms the other shack sets in all areas except perhaps volume. I should build an extra Audio Am for it perhaps but it is fine with phones. It was a free build and I am as surprised as anyone how well it works. It is realatevly unbothered by hand capacity and is selective enough that it has never been a problem. And I do a lot of operating with low power one tube CW transmitters. The Linc Cundall Event is on this week, second stage tonight, and I have been using it for the Rx if choice with the TX I call Big Bertha, a 211 tube Hartley loafing along at an easy 44 watts input. It is fun running the regen with the old gear but it constantly amazes me how much better the regens hear. Instinct tells you it shouldn't be so but experience proves it time and time again. I have come to the conclusion after some 50 years of building a playing with various regens, it is the difficulty of running them that put them aside, not their lack of performance. I am very results oriented. If I can hear on the regen but not on the Digital or even my Kenwood TS830S rx and that does happen BTW, then that is better performance pure and simple. Means a lot more to me as an active ham then 40 pages of spreadsheet and a bunch of squiggly graphs. My worst rx for selectivity although I use it almost everyday is the receiver part of my No 19 Wireless set. It has "barn door" selectivity. None , not one of my regens, is as bad as it is. CW ops in crowded conditions are very difficult with it because of that. I did use it in the Linc Cundall event though Wed night. Hard to follow a signal with it though if here are many around. The digital and the regens dont have that problem. In fact especially the regens following the tone and sound of a particular signal is quite easy as they are all quite distinct from each other.
My interest in German radios stems from my heritage . My name was anglicized when my family first emigrated from Germany to Ireland then North America in the 1700s. It is supposed to be Dolmetsch not Dulmage (pronounced the same) and I know my relatives there in Germany and in Switzerland as well. One from before I was old enough to know was Fritz Dollmatsch (very early spelling but same family) who is listed as an electrical technician in Karlsruhe in the late 1800s to mid 1950s. Karlsruhe is the birthplace of radio experiments (Hertz). I often wondered if he was involved or knew Hertz. Just so we know however BOTH my parents served in the RCAF during WW2. Mom as a Flt SGT (aka "Flight Danny")(rare for a woman to attain back then) and Dad as an instructor of Wireless Mechanics at No 1 Wireless School here in Canada. I got my love of radio from my Dad I think. It was he who told me German electronics are generally very good and not to be sneezed at.

Hello Michael,

I'll go the longer way.
First, check the RegenRx files folder: https://groups.yahoo.com/neo/groups/regenrx/files
https://groups.yahoo.com/neo/groups/regenrx/files

Then look for "solid state regen circuits (LNS)". I think you can use control "F" to search for a folder name.
Inside that folder you'll see a "super-gainer" by GM4MTU.
I copied that from Pat Hawker's Handbook.

I can't tell the edition, but the cover is pink-ish (sort of). Maybe edition #7 or #8.
That's a wild guess.

Sometime I get an error when I past a "long" link because (somehow) a space or CR become embedded in the string. That wrecks the link.

73 to you

Les

Thanks for the links, Bernd.

I am particularly curious about the variable IF filter.

I had 20+ of the RV 12P 2000, but cannot remember
what the equipment looked like. I think it was mostly vhf
as I used some of the "bits" to experiment with vhf
receivers using a Lecher-Leitung - which was useful
in determining received frequencies! Sadly most of
my stuff was disposed of when I went to work overseas :-(

Well, i saw pre-read copies for around $64. I do have the book, but it's "somewhere", and i have to say, it might even be worth $40 or so, new. i was underwhelmed. Large sections are simply copied from U.S. Government wartime publications. As i recall, there were mistakes, and also you can tell that the 'author' is not that familiar with radio technology.
There was a 3-volume series published in Germany in the 1970s, author Fritz Trenkle, publisher Telefunken, that covers German military radio communications systems from 1914 to 1945. These are small format, hardback books, profusely illustrated. I consider these the go-to scripture
on this equipment. A set costs around the higher figure you quote below - when they come up for sale. This set is titled "Die deutschen Funknachrichtenanlagen bis 1945". Fritsz Trenkle also authored books on non-wartime later communications systems and these books are
much more common and much lower priced.

Hello Don,
This posting deals with the topic of specific figures and tests, and the advantages of this method.
You say, " I don't personally care much about specific figures and tests."

Somewhere on the net a Dutch "amateur" posted a series of experiments he conducted to improve the "Q" of a common tuned -LC- circuit. The experiment began with a stock standard tank circuit using a coil (wound with enameled copper wire) and capacitor (variable, stock as you see every day). The initial "Q" he measurement was in the order of 100 to 200 - I don't remember, and the starting figure doesn't matter too much. Using careful measurement, observation and logic, he increased the "Q" (Litz wire, eliminated losses & so on) to somewhere around 1000! In the end he had a different coil and capacitor; but his method is the point of this posting. On many stages the improvement he gained could ONLY be detected by measurement, not by human "estimation". Using this method over about 20 steps he brought the "Q" up to the final figure.

That is my point. When used carefully, measurement is a powerful ally. The application of basic - known - principles got our "amateur" this astonishing improvement. That's why I use quotation marks around "amateur". His approach is truly professional.

I hope to follow his method, and build a "very nice" Jones Superhet.
The first thing I need is a wobbulator.
I have already located the circuit.
I'm on the way.

Les

Well my expression is only mine. Anyone is free to persue whatever they wish. How I came to that point is similar to what I see on sites almost weekly where someone works away calculating searching asking and two years later they almost have a radio but often it is never completed. I was back then (about 1964 or 65 getting nowhere and only adding to my confusion.)in the same boat. It was of all people my Engineer father who dragged me into the daylight. Meanwhile I learned, the same radio could be build in an afternoon or at most a day or so and any minor correction that need be could be done in an hour or so at best. However as I said that is just me and where I have landed after many years of building regens etc. It might not be a spot where anyone else want to be. Thats fine. Whatever floats ur boat.

From: parkerp@...
Topic: 25655 Message: 25655

You might be interested in a regen receiver based on F5LVG's in the latest Sprat but using a 7.16 MHz ceramic resonator. It covers the bottom 120kHz of 40m and is an excellent stable CW receiver. Its 3 transistors adequately drive a crystal earpiece. There are no inductors. I've previously tried VXO regens but this is by far my favourite.

I didn't do a head to head comparison but my gut reaction is that the selectivity is a little broader than an Armstrong receiver I've tried (where there's a dramatic narrowing of the bandwidth as you advance the regen control) but was able to get a very fine regen. You can set it so that CW signals above the oscillating detector are audible as tones but those that are below it are thumps. This may offer a little attenuation, or if it doesn't the thumps are less interfering than another tone.

A video demo is below.

Definitely interested.
But I don't have the latest Sprat.... 165.....
the video says its in SPRAT 158...which I do have....
Is the latest SPRAT article...image... circuit.... exactly the same as
the SPRAT 158?
And ....
the video shows your circuit... your success with your circuit....
so can you post just your successful circuit as a JPG on REGENX ?
That would make it a lot easier then chasing the SPRATs.

Thanks all. Yes, I believe the circuit in the two Sprats is the same although the later one is bigger. Luckily, as mentioned in the video, the circuit is on F5LVG's video. Link in the text description.

My comments about the Armonstrong receiver are generic and relate to any number you see on the web. Particicularly the 1-FET designs.

On this topic I'm reminded by a comment from someone (could have been Charles Kitchin) that FET regens are better for SSB while bipolar transistor regens are better for AM. This has been broadly my experience but I'm happy with the circuit presented in the video for CW-SSB reception. Though LSB reception is suboptimal as you need to advance the regen control slightly more than would be needed if the signal being received was upper sideband. That means the trick I did with CW reception is not possible with LSB.

A regen like this, maybe using a crystal rather than ceramic resonator, might be a reasonable detector for a supergainer type receiver. Although I'm reminded that gain is usually equal about the centre frequency rather than off to one side like it would be with a filtered detector. This could possibly be overcome with an xtal filter or not having the regen detector oscillating at all and using a separate local oscillator to provide the BFO action.

73, Peter VK3YE

25659. Looking for Good Solid State MW Regen Receiver Design?

Yahoo group: regenrx (2016 — 2017)

Topic: 25659 Message: 25659

Hello:

I am new to the list. Can anyone recommend a good MW discrete transistor starter regen design for me? Just something to "get my feet wet." Or, if you think it best to start with a design in one of the HF bands let me know. Maybe later I'd take a stab at one in the 40m or 20m regions.

BTW I built a TenTec 1253 9 band regen back in the 90's, great fun. More recent attempts at tube based "Morgan" style receivers not so much.

Many Thanks

Dave Szasz NV3F

Bigger?
Bigger picture or more components bigger?
But it really doesn't matter ..... especially for Michael with his
jittery y'toob on snailband......
we don't want F5FVG's circuit.... we want to see a picture of your
successful circuit.
I mail ordered some 7.16 Mhz resonators from MINIKITS.COM......
seems they are too obscure to be sold on EBAY like the 8Mhz
resonators... 150 of them for $12.
PLEASE please please post a picture of your circuit.... or email it to
me and I'll post it for you.

WOW cool! Thank you for the heads up.
Mouser price is half as much as what I paid MINIKITS

I had given up on MOUSER and DIGIKEY years ago when their new flashy web pages would not
navigate in my older PC browser. Too bad for them.....I spent money on EBAY instead.

It is encouraging to find Mouser price for 100 is $15.
I will probably do that with the kids
IF I EVER GET A SCHEMATIC of this elusive circuit.
Being an amateur I can't watch a video, pick out the parts, match against a SPRAT article........
I need one final successful working circuit to replicate.
But I am intrigued enough that I ordered the 7.16Mhz resonators.

OK.... soooooo,,,,,,,
sorry for the confusion....
I may have it nailed down now......

I have two images here:
http://www.learnmorsecode.com/help/regen/1F5LVGregenSPART158pg23.jpg
http://www.learnmorsecode.com/help/regen/regen.jpg
which are the same as the attached images... will may disappear or not
display for some people....
so I put screen shots on LEARNMORSECODE.com just for this discussion.

My SPRAT 158... on a DVD in PDF format shows this circuit with PLUG IN
COIL and
the video shows the 7.160 fuzzy image circuit.... a lot of blue
here.... because I tried to clean up my screen
capture to fix contrast.
BUT I can not make out the values of the components in this blue image.
So I was hoping someone had a clean schematic of this circuit.... or
could take this image and RE-label
component values to readable values.

Si amigo ! Yes my friend , you are absolutely right, and when built
many years ago when I was in my late teens it worked very well
indeed... Also a super-regenerative from the same period provided
my first 6 meters band amateur radio two way contact.
The audio section 6J5 - 6V6 was identical on the super-regenerative
that used a 955 acorn tube as the detector... and I also built another
one using a 6C4 detector, both mounted horizontally to make connections
as short as possible...

Greetings,

I am currently working on A Simple Regen Radio For Beginners, as described in the article Charles Kitchin wrote for the September 2000 issue of QST magazine, which available for download from the ARRL website as a PDF. I am building it using Manhattan Style Construction. This is the schematic of the circuit:

This is the layout I used, based on the schematic in the article:

This is a work-in-progress snapshot of the circuit, so far:

I am using a 39 inch long piece of 22 AWG hook-up wire as the antenna. The air variable capacitor is a 365pF. I incorporated the Fine Tuning circuit into the overall circuit. The Coil is 22 AWG solid-core hook-up wire wound around a 1.25 inch diameter pill bottle. I am using a high impedance earphone. I still need to cut out the circuit from the large copper-clad board, and also add a front panel for the knobs.

I decided to test the receiver before doing more work on it. I followed the instructions in the article to get started. At first, I thought the circuit did not work at all. So I checked the voltage points with a DMM - OK. I checked the wiring of the components - OK. The audio section - OK. I still could not hear any regeneration sound at all, nor tune in any stations.

Next, I hooked-up an oscilloscope to the circuit. I tried the 10X probe at several points, and finally got some results with the probe attached to the cathode of the germanium diode (D1). The probe ground is attached to the copper-clad board. The copper-clad board is -9V ground with the battery. With the oscilloscope attached, I could see when the oscillation started, and also hear a faint sound. Then I was able to watch the scope and adjust the Regen knob until the oscillation just stopped. Then I was able to tune in several stations, going back and forth between the Tuning, Regen, and Fine Tuning knobs. So the circuit "works".... BUT only with the scope attached to the cathode of D1. When I take the scope off the circuit, I don't hear anything except a faint hum.

Does anyone have any ideas how I can make this Regen Radio work without the scope attached to it? BTW, I am a relatively new electronics hobbyist, and the scope is brand new, so I don't know too much about how to use it. Any suggestions about where to attach the probe would be appreciated. I got into building Radio Receivers through my interest in Hobby Electronics. I bought the oscilloscope to help in building radios (instead of buying a radio). I am trying to learn as I go, My first radio receiver was a crystal

set (works really well), and this Simple Regen Radio For Beginners is my second radio.

Sincerely,
SC

P.S. This is my first post to the RegenRX Group.

Hi Arnie,

The funny thing is, once a power supply is added, the parts count is about the same as a 5-tube AA superhet!

But the regen is much more fun! ;-)

73,

John

Welcome, Suzie!

The Kitchin regen claims unusually high sensitivity for its simplicity,
but came under much scrutiny because of its floating-diode design :
the germanium diode is in effect open-ended, which in theory wouldn't work.
But evidently it does - presumably because of spurious leakage effects,
which may be why you get signals with the oscilloscope connected in.

If you have other germanium diodes to hand, try different ones.
Also check the coil and components around and including Q1,
replacing them one-by-one.
If you search Kitchin and floating-diode you will find useful info online.

Hopefully someone in the group will have tried this circuit
and be able to offer practical help.

If you do not obtain satisfactory results, try other designs in the
group pages, for example the F5FVG circuit recently referred to
in recent group postings.

Best wishes,

Michael

Dear Michael,

Thank you very much for your reply. I appreciate your suggestions very much. This is my very first Regen Radio Receiver build, and I am very excited to let the Group know that I have got the Simple Regen Radio "working" _without_ the oscilloscope probe attached to it.

The "fix" for the problem this radio was having was to solder a 100pF capacitor to the cathode of the germanium diode (D1) and to the copper-clad board (the ground plane).

Now I can hear the oscillation through the earphone, adjust the Regen knob so it just stops, then use the Tuning knob (C1) and the Fine Tuning knob (R8) to tune in radio stations without the 10X probe of the oscilloscope

attached. Here is an annotated snapshot of the "fix".

There is a slight amount of 'hand capacitance' when I tune the radio, but
that should be fixed when I mount the knobs on a front panel.

This "fix" suggestion was from an Elmer named George who has a webpage about helping Boy Scouts build these Simple Regen Radios For Beginners by Charles Kitchin. He also suggested that I might try putting a 1M Ohm resistor in the same place, and also suggested shortening the leads to the Regen pot. I will try those fixes as well and see which one works the best. But for now, the 100pF capacitor WORKS. Yay !!!

This is the updated board layout, with the 100pF capacitor "fix" in place.

The next step is to construct a base and the front panel. I have some scrap pieces of Copper Roof Flashing that may be useful for the front panel.

Once again, many thanks for your suggestions.
Sincerely,
SC

I'll tell you all about a receiver I built last year. I called it "Uncle Bob's Ion Snatcher" after one of the tube guys who was always there with advice for me. I ended up selling it to one of the members of the local radio club. I played with it for a while and had a little bit of fun with it but decided to move on to bigger and better things.

The receiver used two double-triodes, a 12AT7 for the RF tube and a 12AU7 for the audio tube. The first stage was a grounded-grid RF amplifier followed by a regenerative detector. The 12AU7 provided two stages of audio gain. It provided a good level of audio into headphones.

The kicker was that it ran off of a 24v supply. The filaments of the tubes were wired in series with a 10 ohm resistor. They ran a little cool and the resistor limited the amount of surge current they saw at turn-on. The plates ran from the same 24v supply. You'd be surprised what tubes can do with just a little voltage.

My radio's output stage used a 70v line transformer for the output. These are usually not good for more than a watt of output when used as an output transformer. Why? I'm not sure, as I've used the in setups where the idle current of the tube was isolated from the transformer primary. Nonetheless, it made an excellent output transformer for the radio.

The coils were made using octal bases with PVC pipes glued inside of them. The PVC bore the wiring of the coil and the base...well...you get the idea. It worked very well on the AM band and I remember hearing AM operators on either 160 or 80 meters using a 15 foot length of speaker wire as the antenna.

Here's the video I took when I finished making the thing.

https://www.youtube.com/watch?v=abF9wm42C90

Anyone who wants to build one can feel free. Do it. Do it now.

Sure amigo ! And the reliability of the time proven tubes circuits is
certainly
much higher than solid state devices...
I have tested and operated recently vacuum tubes made in 1935 and they
provided
perfect performance.... very well built RCA original tubes... also tested
Soviet made tubes that date back to 1945, also working very well, no
problems
with complex semiconductor materials migrating and spoiling the performance
in a very hard to understand way...
An 807 tube used on my 1959 first amateur transmitter is still in like new
condition, measuring the same transconductance after more than half
a century.... As a comparison with solid state devices... a very nice
looking
solid state rig has died due to what a local electronics guru describes as
contamination of the inner guts of the transistors possible caused by
defective
manufacturing processes !!! Transistors are not plug in, and changing
all of them
seems to be an unbearable challenge !!!
Also, my regeneratives made with vacuum tubes can operate with rather
low DC plate and screen grid voltages...like 24/48 volts , and still provide
excellent performance....
Finally.... your comment
¨ But the regen is much more fun¨ is absolutely true amigo John

Attachments: 1 described; binary payloads are missing from this source WARC

Is there any standard definition of T1 and T2 specifications?

When you guys see a schematic like this that calls for these two
standard parts:

T1=RF coil of the 4 prong ,plug in type for use with a 140-uuf tuning
capacitor
and
T2=Regenerative detector coil of the 5-prong, 2-winding, plug-in type
with tapped grid winding for electron-coupled circuit

WHAT do you use for these transformers?
WHAT specification would I need to define... to buy or build or measure
these two transformers?

That is good news! Lots of ideas and advice are always available, as you know. There was an error
in the September 2000 QST schematic you followed. The QST article labels R3 as 1k, later versions
suggest 100k for R3, so you might like to try that, with the added 100pF removed. This 100pF might
reduce the sensitivity, so it would be worth experimenting further with, if still necesssary, a 1M
to100k resistor instead, as George suggests. When it is working to your satisfaction, it could be
rebuilt with all the ground points in one place and rigid, short wiring used in the RF section.

Michael

----- Original Message ----- From: Suzie Creamcheeze

Thank you very much for your reply. I appreciate your suggestions very much. This is my very first
Regen Radio Receiver build, and I am very excited to let the Group know that I have got the Simple
Regen Radio "working" _without_ the oscilloscope probe attached to it.

The "fix" for the problem this radio was having was to solder a 100pF capacitor to the cathode of
the germanium diode (D1) and to the copper-clad board (the ground plane).

Now I can hear the oscillation through the earphone, adjust the Regen knob so it just stops, then
use the Tuning knob (C1) and the Fine Tuning knob (R8) to tune in radio stations without the 10X
probe of the oscilloscope attached. Here is an annotated snapshot of the "fix".

There is a slight amount of 'hand capacitance' when I tune the radio, but that should be fixed when
I mount the knobs on a front panel.

This "fix" suggestion was from an Elmer named George who has a webpage about helping Boy Scouts
build these Simple Regen Radios For Beginners by Charles Kitchin. He also suggested that I might try
putting a 1M Ohm resistor in the same place, and also suggested shortening the leads to the Regen
pot. I will try those fixes as well and see which one works the best. But for now, the 100pF
capacitor WORKS. Yay !!!

Dear Michael,

Thank you very much for your reply. I have not seen the errata for the September 2000 QST article. I originally downloaded a copy of the article from the ARRL website.

I can try replacing the 1K R3 with a 100K resistor and see what happens. Now that the receiver is working without having an oscilloscope probe attached to it, I can try just about anything. This is all a learning experience for me.

I am going to go ahead and begin construction of a Front Panel. I have heard that when the knobs are installed on a Front Panel, there is less 'hand capacitance' when tuning the receiver.

One thing is certain, I am definitely going to be building more of these Regen Receivers. I think they are a lot of fun. Here is a first design for a Front Panel for my Regen Radio.

The radio circuit will be mounted on the wood block with standoffs. The Copper Roof Flashing will be attached to the wood block with brass wood screws. I will solder a wire connection from the circuit board to the Front Panel. I can make some one-half-inch tabs on three sides of the Copper Roof Flashing to add rigidity if needed.

Regards,
SC

Good question! I know Hammarlund made ready-wound 4-pin coils that would cover approximately AM BC band thru 20 meters. They also made 6-pin versions covering the same range. But I'm not sure about 5-pin for ECO.

I recommend the Lindsay reprints of the Hammarlund shortwave manual, or the Gernsback little yellow booklets, or an old ARRL Handbook (40s or 50s is best).

Those publications should give you some pretty good ideas about windings.

There are small differences between Arnie's schematic and the one I have in RCA RTM RC-14. Arnie's is probably a little later, and uses a 6K6. RC-14 has a 6F6 and different spec for output transformer, and does not define the two RF transformers at all. Not very user-friendly. I agree that coil-winding info should have been provided.

Regards,

John

I don't have any Lindsay Hmammarlund shortwave manual reprints or
Gernsback little yellow booklets
YET
but I definitely have 40 and 50 ARRL handbooks on PDF.
Got any particular year that you would have me go fetch because you
liked that book more than others?

Sure. Try 1942 or 43, and also '37 if you have those. I'm looking at actual HB's I have on hand. The only ones I have in CD are the 50's. I looked at '56 but that regen uses modified transmitter coils that might be hard to find, and gives no winding data.

Also, do some internet searching and I'm sure you'll find plenty of tube regen projects with coil winding data that are similar to the RCA tube manual schematic.

For a long time I have wanted to build a regen with a tuned RF stage, and this will probably be it. If it's good enough for Arnie, it's good enough for me!

Regards,

John

I don't know what GERNSBACK little yellow books were....
but I found RADIO-CRAFT 1929-07 pdf on
http://www.americanradiohistory.com/Radio_Craft_Master_Page_Guide.htm

which shows a schematic with the description under UNIT DETAILS saying
primary 10 windings and secondary
125 windings over 1 and 1 half inch closely threaded bakelite tube.

Very simple to follow instructions.....
so I was wondering if it was worth replicating over pill bottles or film
canisters.

So what are the little yellow books? Are they on americanradiohistory?
Do they explain how to calculate
these coils?

The Gernsback "Educational Library" booklets were designed for beginners. I don't think there is info in them on *calculating* windings. But they do have winding data for the various sets. Vintage ARRL HBs should be a good reference for calculating windings.

I think you have an excellent idea to use pill bottles as coil forms. Back in the day it was easy to go to the local radio store and buy ready-made coils, or empty forms. Not anymore. Keep an eye out for vintage coils and/or forms on eBay or at local hamfests and antique radio meets (if you're near any of those). Coils and forms do turn up sometimes.

Hi,

I have seen published reports from people who have the equipment and the patience to measure the performance of the hard plastic pill bottles as coil forms and they are excellent. For plug-in applications they can be fastened to tube bases or can be used in bandswitched or single-band radios.

Actually, that link comes back with : Error 404, page not found.

It then says wait a few seconds, for a new page, but that new page has
nothing obvious about how to subscribe to the list.

Topic: 25655 Message: 25700

Hi,
Very interesting transceiver!
It's a new idea without normal VXO or VFO.

And I'd like to make this "Clone" but there is no supplier to sell this ceramic resonator of 7.16MHz in Japan area. It is made by "MURATA" that is Japanese famous component company but we can "NOT" get from my own area. This is really contradiction. hi...

OK you said ... the Australian seller sell it at cheap but the shipping cost is expensive. It's about ten times of the resonator cost. This is also a contradiction isn't it?

I have a ceramic resonator of 3.58MHz in my junk box so I make a doubler using this as an 40m external oscillator circuit and connect your circui. But I don't have a confidence this will work or not.

Do you have any idea about this?

ja9mat Hidehiko.

I found this TRIAC driver circuit on the web.
I wanted to replace the TIC206 triac with BTA25 triac.... just cuz I
have BTA25 triacs now.
Is that OK to do in this circuit?

It specifies a 2SB328 PNP transistor.
I can't find any 2SB328 PNP transistors on the web.
Can anyone recommend a replacement for this 2SB328 ?

Rob, just about any triac or transistor will work. Check your Triac for cold triggering current. A sensitive triac would be nice. Triacs and SCRs have problems when temperature drops below zero. Transistor would be 2N2222A or such.

Go for it! I have built a lot of triac and SCR circuits. I really prefer SCR circuits as the SCR is a more rugged device. A Triac can fail half wave. Not good if driving a transformer. But an SCR and a full wave bridge are extremely rugged. And won’t fail half wave, assuming your parameters are properly chosen.

Larry

Hello Rob.

I see you are sharing your stock of 7.16MHz ceramic resonator.
If you could would you please share for me? I want 4 pieces of resonator for regenerative transceiver and the other homebrew project.
Please let me know the cost including the shipping.

I can pay via PayPal.

Thanks for your support.

JA9MAT Hidehiko.

Not sure on the triac substitution, but if it will stand the voltage and current, it should work fine.

I did notice that when you asked about transistor substitution, you specified PNP. That circuit is designed for a NPN transistor jast as is drawn. The Zener and ballast cap create a negative supply, so the top rail is negative and the lower rail positive...opposite the way such things are usually drawn. So be sure to follow the schematic with regard to cap and diode polarity, it is correct. The transistor only sees the 15V supply as limited by the zener diode, so a 2n2222 should work fine.

I ordered from K5NWA's "The Parts Place" last summer when I started my Beach 40 DSB. He stocks 7.2 MHz Resonators. I bought a bundle of 10 to ensure I'd have enough for various projects.

http://www.thepartsplace.k5nwa.com/index.php?route=product/category&path=68

He also has some cool power transistors there. Try the 2SC5171 or the KSC2690 if you want a low-power transmitter, such as a Michigan Mighty Mite. The 5171 is capable of at least a few watts under 15 MHz.

(I have no financial relationship with the above website and am posting them simply because I got excellent parts/service from them)

25711. OT TRIAC driver replacement PNP transistor thanks for the help

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-29 06:03:15 UTC
From: Rob
Topic: 25711 Message: 25711

OK guys..... this was some pretty darn fast answers from a lot of you.....
THANK YOU!!!!

A few things to note here....
I was given this explanation:
I did notice that when you asked about transistor substitution, you specified PNP. That circuit is designed for a NPN transistor just as is drawn. The Zener and ballast cap create a negative supply, so the top rail is negative and the lower rail positive...opposite the way such things are usually drawn. So be sure to follow the schematic with regard to cap and diode polarity, it is correct. The transistor only sees the 15V supply as limited by the zener diode, so a 2n2222 should work fine.

So that takes care of the transistor.
I did get some more details about triac circuits and PDF files.....
ALL VERY GOOD INPUT for me. Thank you again.

As far as the hazards of AC goes....
YES I am fully aware that this is lethal voltages and must be protected from accidental electrocution.

This particular rundown searching for TRIAC circuitry is an educational experiment for me to learn how to
replace a clicking relay with a solid state device to run a washing machine AC motor and a sump pump.
Again..... all experimental.... nothing that MUST be built..... just a learning process.

25712. 7 Mhz resonators for fun post office rules

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-30 05:22:50 UTC
From: Rob
Topic: 25712 Message: 25712

I had an interesting visit with my local post master today.
He asked me if my letter was machinable.
what he really meant was
COULD MY LETTER PASS THROUGH the USPS letter machinery without
jamming or tearing open the paper envelope.

I handed him TWO different types of envelopes.
One envelope had one sheet of paper folded in thirds and it had
resonators taped to the center of that
folded paper which means it was a little lumpy near where the address is
written on the envelope.
This method is how I mailed most of the shared resonators.

SO IF YOU GET THIS RESONATOR FROM ME THEN PLEASE TELL ME IF THIS METHOD
IS SAFE
OR IF IT DAMAGES THE RESONATORS TO GO THROUGH THE POSTAL SYSTEM.

The second letter was wrapped in many layers of cardboard protection
because it was going to Japan.

25713. Re: 7 Mhz resonators for fun post office rules

From: les.au49@...
Topic: 25712 Message: 25713

Rob, regarding getting your ceramic resonators thru the post - Here in Australia we have a test for a "standard letter". The first deals with the "flat area" of the letter, and is irrelevant here. The second is a slot (probably) 5 or 5 mm opening. (and the width of the letter). A "standard" letter has to slide thru the slot without jamming or significant assistance. It's a simple test. I think a letter that passed this test would be "machine-able". I take the word "machineable" to mean "able to be machined". HA!

Good Luck with the Post Office.

Some time ago I got a package in the mail.
To collect the package I had to produce I.D. I produced my driver's license.
That included a photo of me, the name "Leslie Smith" and my address - the address on the parcel I hoped to collect. So - the Post Office "type" had a parcel addressed to Les Smith, a driver's license (issued to Les Smith) and a photo on the license - a photo of me.

Now, I admit I was in a cheeky mood by that time, since I was a regular customer at the Post Office.
When the "postal type" behind the counter asked, "Are you the Leslie Smith that lives at #36 Macquarie Street, I couldn't resist saying, "No I'm another Les Smith. I stole the driver's license you have in your hand from the letter box of the Leslie Smith that lives at Macquarie Street and then had plastic surgery. Now my face matches the photo of the face of the other Leslie Smith who DOES live at Macquarie Street.

This didn't help. The long line of people patiently waiting behind me fell down laughing.
The face of the women behind the PO counter turned visibly red.
Since then I have been particularly unwelcome.

Now I always go to another Post Office where they ask reasonable questions.

Les

25714. Wide-band RF Chokes

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-30 08:33:43 UTC
From: J Ed
Topic: 25714 Message: 25714

Hello, all,

In a lot of RF transceivers, I see a familiar RF choke type used. It looks like a phenolic rod sized between 0.25-0.375" and has several winding banks on it. These normally come in 2.5 mH sizes but can come in others. I looked up data for such a part once and found that the listed resonant frequency was 1.3 MHz or so.

Either they misrepresent the self-resonant frequency or there's more at work here. If I wanted to make an RF choke for the input of a receiver, for example, I'd shoot for something like 2.5 mH so it would have a decent impedance on the lower bands. Such an inductor would also have such a low resonant frequency that it would be near-impossible to tune higher bands.

One solution I can think of is to place two high-value chokes in series. For example, I could get some ferrite cores like FT100-43 and wind them each for 500 uH. In series, they would be a large impedance (22k at 3.5 MHz) and their self-capacitance would be low enough to reach a higher frequency. Then again, the output capacitance of the RF amplifier tube / transistor would probably cause a resonance.

Would it be better to include dissimilar chokes in series? For example, a 500 uH choke in series with a 50 uH choke? The self-capacitance of the larger choke would likely shunt higher frequencies which would be blocked by the smaller choke.

This has applications in all sorts of wide band RF circuits. I'd need it for pretty much anything designed to cover a large part of the HF spectrum.

Ed AE7TE

I make my own chokes because it is for me almost impossible if not impractical to buy them. For instance minimum shipping is $20 to here. SO, 100 to 200 turns of any fine wire scramble wound works well. I usually use a dowel 1/4 or in the case of POW dump scavange builds a pencil stub. They always work. Aside from the calculations there is also the problems so you know the uh needed but what is that in practical terms? (How many terms of what size wire on what type of core and at what diameter.) So. I pretend I am an electron. I make a winding that if I was trying to dance a RF freq I would say to heck with it because I would be too tired after passing through it. I know crude , unscientific, not good engineering practice or what have you, however, very practical and works, always. When you get to high power it is a bit trickier but usually doable. I have also taken a 5/8 dowel, put it in the lathe and made 3 deep groves with a square nose 3/16" bit in the wood and then filled the grooves with a continuous winding of the appropriate wire (able to carry the current required with a large margin of safety.) This is probably my best solution and is used on my 211 44 watt Hartley for one example. If you don't have a lathe chucking the wood in a drill and using the side of a file will give a workable result. Then , also, since I scrap a lot of Superhets for parts I tried using one of the IF coils and wouldnt you know they work very well. My breadboard 1943 station employs these. Now come the BIG problem. Can something made this easily and simply work. Some will say no. Some will produce a page of math showing it is all wrong (its ok I am apparently "always wrong" although usually successful) or you can try it for the ten minutes or so it takes and discover much to your surprise it s a very practical solution to the problem. Your understanding of the problem BTW is similar to mine to a certain extent. If I had a good supply of those old chokes I would still use them but I suspect performance would not change. However since I don't this works well.

> I make my own chokes because it is for me almost impossible if not impractical to buy them. For instance minimum shipping is $20 to here.

While I'm in favor of making your own components, I'm dubious about your minimum shipping comment. You're in Canada, right? Tthe cheapest shipping to Canada is ... free (if you're not in a hurry).
If you look at Digi-Key's terms and conditions page:

http://www.digikey.com/en/terms-and-conditions
<http://www.digikey.com/en/terms-and-conditions>

You'll find this interesting footnote in section II ("Conditions of Order"), part 6 ("Shipping Charges"):

* When a check or money order accompanies your order, Digi-Key pays all shipping and insurance (our choice for method of shipping) to all addresses in the U.S. and Canada.

Oddly, Digi-Key's Canadian site does not include this verbiage.

It's inconvenient and slow, you have to print out your order, mail it to Digi-Key along with a check, and wait for them to send it to you by the cheapest/slowest method available. But it is free.

While I'm in favor of making your own components, I'm dubious about your minimum shipping comment. You're in Canada, right? Tthe cheapest shipping to Canada is ... free (if you're not in a hurry).
If you look at Digi-Key's terms and conditions page:

http://www.digikey.com/en/terms-and-conditions
http://www.digikey.com/en/terms-and-conditions

You'll find this interesting footnote in section II ("Conditions of Order"), part 6 ("Shipping Charges"):

* When a check or money order accompanies your order, Digi-Key pays all shipping and insurance (our choice for method of shipping) to all addresses in the U.S. and Canada.

"Oddly, Digi-Key's Canadian site does not include this verbiage"
Well I am not fond of dubious as a word about me when I have spent a lifetime endeavouring to always be as factual as possible. However as you said it isnt on the Canadian website which more then likely means doesn't exist here. Even my tube supplier in Hamilton , only 2 1/2 to 3 hours away dings me $20 per order. Some may be less but still significant however the bottom line is when I can make one that functions properly in 10 to 15 minutes why would I go through all that. What would I gain? Absolutely nothing. I know of no one here or there who ships HERE free except perhaps the Chinese Ebay sites. In fact Ebay is littered with sites that say "Will not Ship to Canada" which in beyond understanding or rational. Usually all special shipping deals stop at our border and often say in the Contential USA. I have shipped free to my brother or sister who live south of the line but I still have to go and get it which usually cost $100 or so after I buy them dinner and pay for my gas.
I am not sure Free is in the Canadian vocabulary..;>)

25719. For Sale: 1930's Rationalized Autodyne Receiver and Crystal Controlled Transmitter

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-30 21:52:12 UTC
From: Whitebear1122
Topic: 25719 Message: 25719

I am selling my early 1930’s 80 meter cw station. I bought this from a fellow who got it from the estate of the OT who built it back in the early 1930’s. I’ve probably had it for 15 years. I looked that transmitter and receiver over from top to bottom hoping to find the OT’s call sign written in there. I couldn’t find it. Maybe you can. I planned to restore it and put it on the air but I never got around to it. I know there is real 1930’s electrons stuck in the tubes and wiring. The transmitter uses a nice big fat crystal so I know it was early 30’s. The OT’s receiver I believe is the ARRL Rationalized Autodyne by George Grammar, and that came out in QST January 1933 so I’m thinking 1933 to 1934. The set up is for 80 meters. I put pictures of the transmitter and receiver up on photobucket.com <http://photobucket.com/> at this location:
http://s1140.photobucket.com/user/651daisy/library/1930s CW Station <http://s1140.photobucket.com/user/651daisy/library/1930s%20CW%20Station> for your viewing

This album shows several pictures of the receiver and the transmitter.

On the transmitter, the plastic supports for the 80 meter coil long ago disintegrated. The transmitter came to me with the coil laying flat on the transmitter because the plastic supports disintegrated and the coil just laid down as it sat on the OT”s shelf forever. I bagged up the coil in a Baggie because it can be easily restored. The coils are plug in coils so I imagine this transmitter can be made to work on 160m and 40 meters as well. Just a guess.

The receiver has a snazzy National teardrop style vernier dial on the front. It has two Hammarund ceramic plug in coils marked 3500 on them.

I don’t know anything else about them. They’ve been sitting on my shelf for years. They would be fabulous to restore and put on the air if you want. If not, they have a lot of original 1930’s vintage parts in them if you decide to build your own transmitter and receiver. A lot of these parts are “unobtainium” these days

Asking $200 for the pair plus shipping. Thanks, 73, Scott WA9WFA

25720. For Sale: 1933 Rationalized Autodyne Regenerative Receiver

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-30 22:11:52 UTC
From: Whitebear1122
Topic: 25720 Message: 25720

Seeing what I believe is a Rationalized Autodyne regenerative receiver from QST January 1933. It is built in a nice wrinkle finish cabinet with lid. It uses a National SW-5 style dial and bezel. There is some damage to the dial plastic. It looks like the OT put it too close to the audio tube and it did a little melting of the dial material. Bet that really irritated him :) That’s what he gets for putting a hot tube that close to the dial :)

I bought this maybe 10 years ago with the plan to strip it for parts and build my own Rationalized Autodyne but I never got around to it. I put photos of it up on photo bucket.com here:

http://s1140.photobucket.com/user/651daisy/library/Rationalized Autodyne Regen Receiver <http://s1140.photobucket.com/user/651daisy/library/Rationalized%20Autodyne%20Regen%20Receiver>

Asking $125 plus shipping. Thanks. 73, Scott WA9WFA

25721. National SW3 Model III

Yahoo group: regenrx (2016 — 2017)
Date: 2016-01-31 01:39:04 UTC
From: Whitebear1122
Topic: 25721 Message: 25721

Hi, I put up some photos on photobucket.com of my National SW-3 Model III. The model III was the last model made with manufacturing up through 1944. I casually looked 25 years for this model. I've consulted with a few experts and we've noted that there are 4 known examples of this out there. I'm not surprised because in the 1940's Superhetrodyne ruled. I've heard that the SW-3 Model III continued to be made that late into WWII due to it's simplicity, reliability, low cost, for use in Marine ship to ship, ship to shore communications. I've heard the term "banana boats" in those discussions.

The SW-3 Model III differs from the earlier models I and II by adding a factory B+ switch and headphone jack to the front panel, the antenna and ground opening moved from the rear to the left side rear., ceramic octal tube sockets and octal tubes. The Model III also had a new version of coils specially for the Model III. I have a band spread set for 20m, 40m, and 80m with the original boxes. I also have the dog house supply 5897 that accompanied this SW-3 when the OT bought it.

Here is the link: http://s1140.photobucket.com/user/651daisy/library/National SW3 Model III <http://s1140.photobucket.com/user/651daisy/library/National%20SW3%20Model%20III>

I thought you would get a kick out of seeing such a rare model SW-3.

73, Scott WA9WFA

I'm sure the SW-3 would not be used in any ocean crossings during WW2 on U.S. ships.
The receiver is not found in the FCC's list of approved receivers.
The British seem not to have worried so much about this - old style regens such as the Marconi 730 were used even past the war, according to an account i read of an English freighter sinking in 1947 - it had this receiver and a SPARK transmitter.

I think Alaska Steamship MAY have used SW-3 throughout the war ONLY on their 'inside passage' route from Seattle to Alaska points. I know their ships used the SW-3 as an LF receiver only, and Sargent model 10 regens for the HF. I believe the SW-3s replaced Alaska Steam's older IP-501 receivers in late 1941. Per maintenance papers i have, which don't explain why things were done.

There was a whole lot of war(s) fought long before anyone under FCC rules even thought to get involved.
I recently read a long dissertation on the use of regens on ships and some of the unprovable myths surrounding their detection. British and Canadian ships had what amounts to a Farady cage around the radio room. I know the HRO was used as was the CSR5A (used to have one, NOS even) Very early radio rooms had a regen of sorts probably up to 1939 and it was known for its incredible sensitivity. My brother has a mid WW2 Canadian Navy RX with a short HF band group. I get him to check signal strength for me sometimes with it. It is a rare StewWarner piece made right here in our town about 1942. Factory is still there.
Have you used the SW3 much and if so what were your impressions?

Yes, we had fear that the Germans could df on receiver radiation to find our ships, and went to elaborate tests to qualify receivers. Several years ago I corresponded with retired German RO's, and learned that they knew very well about receiver radiation, but realized they would have to be within a few miles of the ship, at which point they could see it. Their underwater listening gear detected ships at 20 to perhaps 50 miles, was reliable, and gave useful information about the type of ship, etc. The real reason was electromagnetic compatibility aboard ship; with dozens of receivers running you can't have them listening to local oscillators.

When German subs began being surprised on the surface in spite of no warning from their radar detection receiver they thought we were detecting radiation from their receiver, and did tests. They found it could indeed be heard at a distance, depending on the altitude of the plane. The real reason was we had gone to microwave radar, which was not detectable in their radar warning receiver.

Military secrets don't remain secret for very long, Zum Beispeil, (for example) microwave radar. When 'planes went down they were immediately searched for new technology, analyzed, then neutralized and utilized as soon as possible.

We discussed this at length over on the milsurplus group. The myths you mention arose because of the panic in the early months of the war, when Allied ships were easy pickings for U-boats and ideas for countermeasures were lacking. The regen receivers only danger was that they
MIGHT interfere with other radios in the same ship or maybe nearby ships. The FCC had a list of approved shipboard receivers and a list of banned receivers. It seems kind of crazy now, but there it was.
Meanwhile, British ships didn't have a strict list like this, and even the U-boats
had an entertainment radio (R3) that wouldn't have passed the FCC's rules. As an example of the level of fear in the USA, in a LIFE magazine article from WW2, it says on the run from Seattle to Alaska, which was even all coastal sailing, use of electric shavers was forbidden -
U-boats
MIGHT be able to DF them!
Ships in ocean convoys didn't use radios. They signaled using flags, blinkers, or VHF radio at 72 MHz, so U-boats had nothing to radio-track on.
The myth is almost dead, almost.
-Hue

Zum Beispeil (Es ist OK, Ich verstehe)
Well tests I did here on my own regens suggested that detection beyond even under a hundred feet is very difficult. However I know the fear of the unknown and desire and need to error on the side of safety is the way to go. The No 19 WS with its odd Cw set up (Key in to transmit and out to listen) runs the osc constantly and can be easily heard although faintly on a nearby rx. That surpises me as on AM no such problem exists the Tx is OFF. So you have to always use the No 19s RX to listen otherwise you will be listening to yourself too even though the key isnt pressed. must have been the "new guy" who designed that set up. Regens saw a lot of milt service in some forms on both sides. I have a German Spy locator radio, leather satchel and all used for detecting clandestine ops. It is NOS so I have refrained from firing it up as I don't want to injure it. The manual has been translated to English and the pages glued in then mimeographed but the pages still say blatt 3, blatt 4,

I have always been curious about the apparent fear of
detection of a WW2 regen. It would surely have been feasible
to surround the oscillating detector with solid shielding
and to front it with a grounded-grid RF amp. Very little
RF would "escape", which could have been verified in
laboratory tests. Or not???

OT : if Thunderbird experts are eavesdropping,
I am in the process of switching to W10 and TB. I would
like to totally deactivate the infuriating junk filters,
ie let everything through. It is quicker to glance at all
incoming than to have to check junk and trash folders for
valued missives which TB has condemned. I have tried
the following, without success :-
1. Tools > Acc Settings > Junk settings : untick
2. Help > Troubleshooting > Profile folder > Training.dat : rename
3. Options > Advanced > Config editor > mail.adaptive
filters.junk_threshold : reset to 999

Anything else I could try?

Michael

Fear, yes. I've read reports, towards the end, of German commanders shutting down radio for fear of detection, to much disgust by the radio operators.

Hi,

The fears and the steps to combat the fears were certainly real enough. I have one of those magnificent regens built RCA for the US Navy and designed just before the US entry into the war. There are two (count 'em 2) RF amplifiers (just for isolation and not for gain). It's a 2-v-3 regen (not counting the three tubes in the power supply). There is planty of shielding. A metal box inside a metal box with addition separate shields for the parts. I can connect the antenna terminal directly to a GC receiver and NOT hear the oscillating detector. How good is THAT!?! The regen can hear the BFO in the *pretty*, modern superhet quite easily. Looking back we know the hysteria was much ado about nothing. At the time is was a life & death struggle.

The concern about receiver radiation is not directly from the receiver, rather from the antenna. With an rf stage, energy from the oscillating detector, or superhetrodyne local oscillator, (more likely) can couple back through tube inter-electrode capacitance, and stray coupling, to the antenna. Without an rf stage it's worse, but probably not significant. With good construction the problem, if any, is insignificant. I have two RAL regenerative receivers with two rf stages, and when connected back-to-back, I cannot hear one oscillating in the other, even at 23 Mcs.

Hi Richard,

One of these days I will remember to do the same check with antenna terminal to antenna terminal with later superhet and the SW-3. The SW-3 has only one rf amp (1-v-1). I initially attempted to make a tuning chart for my RAK by using the superhet (and later an LM) to spot the detector frequency and plot that against the dial log. I ended up having to use a signal generator with a frequency counter so that I could spot the generator signal with the RAK to build the tuning curves. Nothing else could hear the RAK. The RAK could hear everything else.

Maybe I will find the SW-3 detector is easier to hear with superhet and the LM.

There was a National receiver which had a "radiation-suppressor" unit
installed for that reason.
I think that was the NC-100. (RAO in Navy use.)
There was a suppressor unit add-on for the Halli SX-28 receiver; i have
never ever seen one tho.
Without it, the SX-28 was ruled not acceptable on any ship. The
"airborne SX-28", the AN/ARR-7
receiver, had an additional untuned RF stage as a radiation suppressor.
Then there were the Scott receivers RBO and SLRF and SLR-20, all built
to comply with the FCC's
specifications. The SLR i believe means "Special Low Radiation".

Hi Arnie and others:

In this group you and others have expressed the need to have a grounded grid first stage along with attenuators. The design you have written about in this email does not have such a feature. Is there not a problem with overloading the detector due to the rf amplifier front end without any attenuators?

Regards,

Raj

It was a rumour among navy men that the Germans could hear a receiver at 100 miles.We now know that is unrealistic but how could you be sure back then. Now in the comfort of it not being life threatening we have the luxury of thinking it through. First anyone who has run a regen on battery power knows how little B voltage it actually draws. Using ten 9 volts I regularly get 6 months to a year's use. If I was transmitting appreciable power I would be lucky to get an hour or so..Then there is the case that can be made that a regen does not like to be hooked to a reasonant antenna as it will have trouble functioning. This is one of the main causes of the so called dead spots. So next time you fire up your low power transmitter hook it to a non reasonat antenna and see how far you get. Probably not far. Anyone who has run early vintage I tube gear or QRP knows everything must be right if you expect to be heard. Otherwise your power is quickly swallowed up in loses and probably wont make it across the road. However how sure can we be? Sure enough to bet you life on it? And we know noise levels which we all deal with can ruin any communication and low power like a few mW simply doesnt cut it most of the time. Back in the 80s I made a CW reconstruction deal. It was a 741 op amp, a clipper reverse paralleled 1N94A s feeding a hi-pass low pass active filter which drove a opto-isolator circuit which keyed a peizo buzzer. I could pull nothing signals out of the mud and recreate them as clean clear signals with the peizo buzzer but it took a lot of fiddling to get it working. I remember my younger non ham brother made fun of it and said he saw no point in it. In a fit of mid 20s rage I destroyed it. That was pretty stupid I know now but I was a slow learner about life. Whether it would pull regen faint signals out of the noise I dont know as I never tried it. It would recreate signals you could only just tell were there. Seeing as how I am a mech/ machinist and only hobbyist it is maybe not a stretch that someone who actually knew what they were doing in electronics could at least increase the detection capability dramatically is perhaps not too far a stretch. It is a deep and interesting subject anyway.

Hello Dave,

I suggest you look at two articles.
(1) In 1968 the ARRL published a 3 transistor design (JFET) by Lange.
(2) More recently Charles Kitchin published an article "High Performance Regenerative Receiver".

Both articles are easily found on the net. Filetype is pdf.

Good luck - good building!

Les

An alternate place to look would be one of the three "Desert Ratt" articles.
This uses (if my memory is correct) bipolar transistors.
I'm not certain if it covers the BC band.

Well,they could have run some tests and put the whole thing to bed. When you have ignorant people making decisions that's what happens. We see that today too, ignorant politicians making stupid decisions. Every era has some public stupidities, but they are becoming too expensive. Enough.....

Les:

Thank you for your help thus far on the project. I am familiar with the 1968 design, and am tempted by it since I have a copy of an ARRL handbook from the mid 60's that includes it presently moldering in the closet. Maybe as a next project if I can track down the old transistors (or modern equivalents) to build it? I was also tempted by other more recent solid state regens but want to stick with discrete parts. Perhaps I'll only to use an I.C. for the audio amplifier.

So I am slowly gathering parts for the "Moorabbin". I had some trouble finding the 160pf variable and thought of either building one from scratch or tearing down a 365pf to build it. And a small collection of long ferrite rods should be arriving in the mail soon. I'd like to read the Amateur Radio Magazine articles but don't know if the WIA offers reprints.

Also, I may include a cheap chinese kit frequency counter loosly coupled to the set on oscillation as a readout.

very exciting!

Cheers & 73's
Dave NV3F

Substituting Bipolar transistors is pretty easy, and there are only a few pitfalls to avoid if you are not trying to get them to work at VHF or somethin' silly. The main thing is to match either PNP or NPN. Then small signal or power type, and it has to stand the voltage, but at 12V or less, any Si transistor will do. You need to be able to have enough Ic, but too high a rating will be a big die that may not have good frequency response, so more is often not better.

1960s might be a little early of a choice for a transistor design. In that era most everyone learned the craft on tubes, and there was some hollow state thinking that didn't always work so well. You pretty much never want to bias a base-emitter junction with voltage like you would a grid for example...you want to establish a base current. Books and articles of that period warn again and again about thermal runaway, which isn't hard at all to avoid if you think current instead of voltage, and they are cheap, so you can use more of them or bigger die, and so you shouldn't be tempted to push them to the limit...but tube designers were always trying to save a tube.

It is worth remembering that it is signal/noise that determines if you can copy a signal. It isn't so hard to hear a whisper in a library, but in a crowded discotheque you can go hoarse trying to have a conversation.

The EM ambient noise level has increased notably just in my lifetime, I'm certain it isn't just nostalgia.

On the open seas, you are a long way from any QRM sources. I suspect that not all of the fear of detection was unfounded. As I understand it, there was a standardized distress frequency (was 500 kHz for shipping later on, before the satellite era.) so the Germans knew right where to listen. As that receiver wouldn't normally be used for traffic, the regeneration might be left a little high to insure there was still a beat note if the set drifted a little.

Hi,

We already have the reports from after the war that make it clear
listening for oscillating detectors was NOT practical. Sure you can
probably here them - after you are already eyeball to eyeball with them.
The submarine warfare threat was terrifying and a matter of life and
death. They weren't taking any chances.

Long ago i read a couple things that also have weight on the subject. I read that at the onset of WW2, English that still had WW1-era regen receivers, i mean simple things with no RF stage, had them changed out for receivers with less chance of radiating. Shipping companies tended to keep in place what was working; why spend more money? Some of the older regen ship receivers were REALLY simple, like 2 tubes. However, their replacement doesn't mean the end of regens on British ships; i have two that made it through the war, in service. They are NOT as elaborate as U.S. receivers; they are 1-v-2 circuits, i mean 1 RF, detector, 2 audio stages.

The other item was an article in 'Sea Classics' magazine. In the memoir of a U-boat crewman, he said they had listened for the 2 MHz voice communications between convoy ships, but heard nothing. Radio communications in convoys had been moved to visual signaling or 72 MHz short range, low power voice. This U-boat crewman did NOT say a thing about listening for ship's receivers. I am sure they DID listen on 500 kHz for SOS and SSS (sighted submarine) signals from individual ships not sailing in convoys - that would be coastal or Caribbean. Everyone listened on 500 kHz, even SWL listeners.
One man i spoke with, many years ago, told me that on the West Coast USA, at times they could hear ship SOS signals from the Atlantic.

G'day all,
I'm surprised no-one mentioned SOE agents working in occupied France using the Paraset. The Paraset receiver is a 0-v-1 "thingy", and the comms procedure was this: (as I understand it).

The "agent" was issued with crystals - her transmitter frequency was set, and known at Bletchley (or wherever). Communication began with England calling, on a pre-assigned frequency. The agent listened to England on this frequency. Clearly a "regen" set could NOT be easily heard. It is impossible that SOE would have overlooked the possibility that the Abwer (or Gestapo or whoever) would listen for the receiver at this time, had it been possible to "hear" the receiver.

Beyond this, consider the maths. The detector in a regen set might draw 1mA. If the receiver ran a +250V B+ line that would amount to 250mW IF ALL THE POWER WENT "UP THE STRING". The Paraset detector "tube" is type 6SK7, operating in the Hartley circuit. The screen grid voltage is varied by 20k pot. I never measured the screen grid voltage in a Parset, but in a receiver I built using a 6AK5 pentode the screen sat at between 12 to 15 volts when the set was oscillating and properly adjusted. Because the plate has little RF on it (and screened from the control grid, G1, by the screen grid, G2, that means that the DC input to the detector would be around 12 to 15mW. Of this, only 60% would be converted to RF, and after that there is the question of how that could be coupled effectively to the aerial.

This is the note from a "guide to the Pat Hawker papers".

"John Patrick Hawker MBE (1922-2013), G3VA, popularly known as Pat Hawker, was a professional and amateur radio engineer, who during the Second World War was actively engaged in British Intelligence services, and Is associated with the Bletchley Park code-breaking center, working with clandestine radio to support resistance units. Hawker was involved in many aspects of radio, beginning in World War II as a member of the Radio Security Service (RSS) and its connections to British Security Service Military Intelligence Ml5 and the Secret Intelligence Service Ml6. In 1941 at the young age of 19 he started at Bletchley Park as an intercept operator. The bay he worked in contained two HRO receivers, each operator being given a specific list of signals to listen for. In April
1943 he was transferred to Section VIII unit, and served at Weald Station as a two-way radio operator, under Morse code expert Captain Robert Henry "Harry" Tricker. In 1944 Pat joined unit SCU9 and was sent Into war zones where covert communications were required . After the D-Day Allied invasion of Europe in June, with the small mobile unit headed to Normandy under the direction of Tricker who was now a Major, Pat went to Normandy, where he remained until August. He subsequently travelled to Paris, Brussels, Eindhoven, etc. and into Germany, with the same British intelligence services unit, mainly to report German troop movements and to connect 21st Army Group with Secret Intelligence Service field agents and SUSSEX intelligence teams."

My point here is that SOE (and co) was staffed by well informed types, like Pat Hawker. He would be aware of the point I made above. I need press this argument no further - the conclusion is obvious.

To end where I stated: I'm surprised no-one has made this argument in this thread before now.
I'm confident the receiver wasn't a detectable link used by Germany during WWII.

Very valid point, Les.
The only thing i would add is, that it seems the Paraset was rather little used in Europe itself. Norway, yes, but then the level of clandestine radio
transmitting from Norway pales compared to the numerous stations in central and eastern Europe.
For one proof of this, i recommend "The Clandestine Radio Operators", by Jean-Louis Perquin; book published in France. MANY never before seen by me photographs of the operations; MANY color photos of numerous types of equipment by all western Allies. (Early editions of "Two Eggs On My Plate"
show the Paraset in use in Norway. Two eggs served to the agent for breakfast was his silent message that his insertion into enemy territory was soon
to happen.)
I recall an article by Pat Hawker in 'Monitoring Times' magazine, U.S.A., now defunct. He described the capture and turning-around of a German
stay-behind agent. There's a photo of the agent's radio, and it's a type SE 110/8 (i think that's the nomenclature). The receiver in this was a 1-V-2 regen.

Hello Hue,
I know nothing about this. Pat Hawker wrote a tribute to John Brown in British Vintage Wireless Society - Volume 18 #1 (Feb 1993). In this he writes about the various sets used in France, the problem involved with each set, and so on. One point made was that the Germans listened for key clicks and even a marginal dimming of light globes as a transmitter was keyed. If you want to find this, use keywords "Pat Hawker" and "John Brown" or BVWS with Google.

Hi Les,

The figures I have for current drain on the B+ for an oscillating detector are in microamps and power in higher microwatts. If *all* of that is in the generated rf signal and *all* of that reaches the antenna and the antenna radiates *all* of it somebody 'might' be able to RDF it beyond the range where they could hear the mechanical sounds of the telegraph key in action. Just personal observations with the information that *I* have. YMMV. It's more likely the transmitter would more subject to RDF success.

Thanks for the lead ! I surely will look for that interesting article.

Years ago, i was told by Arthur Gibbons, now deceased, about a case in Gloversville, New York state, probably 1942.
Some odd people had rented a house there and seemed to come and go, but never moved in any furniture or seemed to actually live there.
One of the neighbor women was listening to a radio serial program, so called "soap opera", and she heard rythmic clicking noise in her radio which she smartly suspected might be some kind of telegraphy. She took her suspicion to the nearest Navy recruiter, who in turn contacted Naval Intelligence (O.N.I.) who in turn contacted the F.C.C. A raid was staged on the house but this same woman was alrready standing outside
watching the house and waiting for the F.C.C.; the people in the house fled, leaving some of the radio equipment and batteries. (Oh yes, one key item, they had never had the electricity turned on ! seems pretty dumb!) I have read a bunch of accounts but nowhere found this incident. It may have been that the agents (spies) were rolled up later and this miss just forgotten. 'Someday' i'll write up an article on it
with some supporting materials. But the point is yes, "key clicks" from the transmitter could be detected at some distance.

Just a point of possible interest. If you look up 'CMS radio' you'll find articles and photos of the U.S. Navy type CMS radio from early WW2. The receiver part is obviously for clandestine use, and it's a 3-tube regen of simple design - no volume control! And, no one knows the why or where of this set! It seems never to have been used, except maybe for training? My suspicion is that it was a stopgap set for coastwatchers and the Philippine resistance, but was never issued due to requiring too much 'ham radio' knowledge to use it.

In those days QRN was considerably less than it is today so the possibility of detection of weaker signals was a lot higher with a sensitive receiver.
Having said that, I still receive mW signals from Europe and the USA on 10MHz but now of course it is all digital decoding.

I suggest the mechanism of this working was that your crystal radio antenna was reradiating radio waves, including the wavelength your parents'
radio was tuned to, and your jiggling the detector contacts "AM modulated" the reradiated signal. The reradiated power is very low, but it may
be enough for specific cases. I think Popular Electronics had an article on this once, even showing how you could voice modulate the reradiated wave with no power on your part required. In the Cold War the Russians even had a 'bug' in the U.S. Embassy in Moscow that used this principle. The 'bug' was powered by a microwave signal. The beauty of this scheme was that by turning off their microwave transmitter, they could de-power the bug - it no longer 'transmitted'.

When I was a kid back in the '30's, I used to play with my crystal set at night after bed time. My dad said he always knew when I was doing that instead of going to sleep because he could hear the scratching on the radio as I probed the crystal. The only connection I could figure was that I was using the water pipe as a ground, and so was the neutral of the AC power. This was before polarized and 3 prong plugs.

When I was a kid back in the '30's, I used to play with my crystal set at night after bed time. My dad said he always knew when I was doing that instead of going to sleep because he could hear the scratching on the radio as I probed the crystal. The only connection I could figure was that I was using the water pipe as a ground, and so was the neutral of the AC power. This was before polarized and 3 prong plugs.

I read somewhere that RO's in the 20's and 30's could hear regenerative receivers 30 miles at sea. It's hard to believe, but if your triode regen has 250 volts on the plate and you don't know what you're doing (likely) you could transmit a potent signal.

Richard, AA1P

My only experience with detection of nearby oscillating regens was when we lived in an apartment in Brooklyn, NY back in the late 1930s. We had a midget AC/DC superhet in the kitchen, and often heard loud whoops and whistles of regens interfering with our listening. We never knew whether they came from neighbors next door or across the street or further away. In those days, the superhet was gradually taking over, but there were still many regens in everyday use and their antennas were often crossing each other on the roofs of the apartments. Mike, W6MAB

That would be one of the WW1 and 1920s style 0-v-n type regens with no RF stage. They COULD be used as transmitters especially if you turned up
The regen. BUT they didn’t use 250 volts on the plate, that is unrealistic. And they were battery powered, so the B+ was more likely at most 67.5 – 90
Volts. And the antenna coupling would have to be run close.

I once built a regen with a 958 acorn tube back when we only had 3 radio stations here. I found that I could substitute a carbon mike for the headphones and transmit a signal to a radio up to 50 feet away. Irritated some people.

That is certainly true. In some cases the only circuit difference is the regen pot and phones. Bypass them and you have a transmitter . I have played twice with such circuits. Both were 56 tube based hartley regens and a bump in voltagefrom bypassing phones and regen pot wiper turned them into a Tx instantly. So if an op had a tendancy to allow the regen too much R it would increase the range. I guess we have been all assuming properly run regens. Forgetting probably all of us have once or twice had the R up too high ourselves. Bypassing the phones and pot actually works pretty well for making it from a regen to a transmitter. With a good dual voltage power supply and some careful switching it can be a fairly practical rig. And then I have never been at sea for long and not with a radio but I suspect QRN is not as high with no powerlines, no neighbours tvs no buzzing transformers at a nearby pole and no noisy street lamps. Is there a noticible difference? Someone must know.

HI everybody,

That brought back a flood of memories. I was fortunate to know John for many years as member of the Havering Amateur Radio Club. John was a kind and friendly man who did everything possible to encourage and guide young engineers like me and I remember listening with awe to his lectures, and the more informal sessions in the pub after club meetings.

I still have several treasured possessions that John presented to me as a thank you for the lectures and seminars I gave at the club.

I inquired about this point with several retired RO's, and - it depends on the ship. Some are very quiet, and some have substantial ship-generated noise. My guess is older ships with DC power systems were worse, with DC motor commutator noise. My AR-8506-B receiver (ac/dc) had an optional power line filter for that purpose. A friend who was in the Navy said it was very quiet at sea

Any use to someone here?

Pair of Real 40m LC antenna traps - by SAVOY ELECTRONICS - they look old and unused.
There is a hairline crack in one case, so it could be reinstalled in a different box. Hence the
super low price.

Picture here:
http://af4k.com/imag/ham/traps.jpg

Details at:
http://af4k.com/miscpart.htm

Will sell the pair for $25.00 plus shipping.

G'day Dave, When I read your posting about John Brown, and that you knew him, personally, I nearly fell off my chair with surprise! This is surely connection with history! I would like to hear more about him, and the technology of those times - both before, during and after war - into the 50s. I imagine at that time "radio" was quite different from now.

Even by the 60s "radio" had changed considerably. I lived next door to Geoff D'Emden, VK7ZAS. I was about 14 years. He helped me build the my first regen receiver. It was (this will surprise you, no doubt) a Twinplex, straight from the ARRL handbook. Now to the interesting bit. I complained because I couldn't "hear" (I mean resolve) the weekly broadcast from the local branch of the WIA (Wireless Institute) because IT WAS SBB. I remember clearly, that Geoff said, "Yes, I told them to stick with AM for the broadcast." The point here is that a properly built regen can resolve SSB, but (it seems) no-one was aware of that. Consequently, over the next decade, there was a substantial move toward commercial gear. I'm interested in that sort of detail.

Returning to the topic of John Brown, I'd like to hear more about this fellow and those times. We have, I believe, a good deal to learn from history.

73 to you!
Les

I have a powerhouse regen which has a cathode driven (GG) frontend. overdriving is not a problem with it. It is not though a very good regen design. Fine for SWl ing but almost uselesss for Ham use except in really good conditions. The older I get and the more regens I build I keep going back to one design for tube rigs that is to me superior. The Twinplex and variations there of. All the others work but not any better and rarely as good.That has been my experience so far . I built my first in 1965 I think and my last two weeks ago. donVe3LYX

I would think there would be little chance of overloading the detector with a grounded grid amp. The gain is rather low. And besides, a pot in the grid or cathode circuit could attenuate the signal to whatever level you want.

I was referring to overloading in the regen design that Arnie posted which did not have a grounded grid amp front end. Amplifying the incoming rf before detection could lead to overloading the detector is it not? Or is this not a serious problem?

Thanks.

Raj, I have built several regens with grounded grid and grounded cathode amp front ends and have had good reaults with both. The best result was with a tuned RF amp front end. The detector can be easily overloaded, which is why a means of RF attenuation should be provided. It's easier to reduce a strong signal than to increase a weak signal.

A very simple input attenuator.... just a 1000 ohms linear carbon
potentiometer
one leg to ground.... the center to the grid of the RF amplifier stage via
a small ceramic capacitor , and the top connection goes to the coax
cable center conductor...
The RF amplifier UNTUNED.... a triode....
ground the cathode....
a grid resistor of 10,000 to 33000 ohms (not critical at all)
the plate goes to B plus voltage via a 100 kilo-ohms resistor
and the output is coupled to the antenna coil of the regenerative
detector via a small capacitor....
You can also try a grounded grid RF amplifier....
My best direct regenerative, not a regenerodyne uses a RF amplifier
stage, one Hartley type regenerative detector with screen grid
regeneration control.... and a dual tube for audio, half a triode
and the other half a tetrode... that is a 6BM8/ECL82...
Coils are hand wound for frequencies from 500 kiloHertz to about
20 megaHertz....
Hope this helps...

>

Dear Michael,

I have "finished" the Simple Regen Radio For Beginners (if a home-made radio can ever be really "finished"?). I worked on the Front Panel. I attached a ten foot piece of wire to the circuit board (as a counterpoise to the 39-inch wire antenna). I also attached a wire from the circuit board to the Front Panel. Here are a couple of snapshots of my first Regen Receiver.

The knobs are (from Left to Right) Fine Tuning, Regen, Volume, and Main Tuning. The ON/OFF switch is on the left side.

The Pill Bottle is 1.25 inches in diameter. It is attached to the circuit board with a #6-32 brass machine screw and nut. The Main Tuning capacitor is a 365pF air variable capacitor, purchased from Antique Electronic Supply (https://www.tubesandmore.com/). It is the most expensive component in the radio. The battery clip is also attached to the circuit board with a #6-32 brass machine screw and nut. The standoffs are plastic cylinders from Dental Floss.

This was a fun radio to build. I started off with the schematic from the PDF article, and slowly transformed it into a layout for Manhattan Style Construction. All of the layout work was done in a graphics program called Kolourpaint, which is VERY easy to use, and has all the tools needed for doing this type of drawing. Here is the final layout (including the FIX I used to make my radio work).

The farthest station I have been able to hear with this radio, using the 39-inch wire antenna is Radio Havana Cuba at 6000 kHz. I consider this first Regen Radio build to be a success.

At this time I am working on the layout for a "Desert Ratt 2" Regen Receiver. I think I am hooked on Regen Receivers for the foreseeable future.

Sincerely,
SC

Good to know, Suzie! Did you notice whether R3 was better as a 1K or
100K resistor?
Once you get "bitten" you will certainly want to try all the
best-reviewed regen designs.
The Desert Ratt is anoather tried-and-tested design.

Dear Michael,

Oh My Goodness, I have a whole list of things to try out on that radio, but I haven't gotten around to any of them, yet.

I am already drawing the Manhattan Style Construction layout for the Desert Ratt 2. I have decided to follow Dave Richards' (AA7EE) version of the DR2. I like the idea of trying the reduction drive that he uses for the Main Tuning air-variable capacitor. I'm not sure I will be able to find all of the same parts as he did for his DR2, so my version will probably be slightly different.

It took me about three weeks to draw the layout for the Simple Regen Receiver For Beginners. After the layout was finished, it took me just a few days to construct it. So I am accustomed to spending a long time drawing a circuit. I enjoy drawing.

BTW, that radio was the third circuit I have made using Manhattan Style Construction, and it was much much larger than either of the first two. This next radio will be the fourth circuit I have built using MSC. I like MSC for two main reasons: no etching, and no drilling holes for components. The only holes I had to drill in the circuit board were for the brass woodscrews for the standoffs.

In the past, I have etched my own circuit boards, and drilled the holes for components, and it is a mess and a bother.

If I may ask, what are your favorite Solid State Regenerative Receiver designs?

Sincerely,
SC

Nice work -- a couple other fun solid state regens to feed your addiction --

Ozark Patrol -- I did mine homebrew from the 4stateQRP schematic. nice result from 3 NPNs -- its barely more complex than the old Radio Shack regen but the simple reflex circuit sounds much better than any of my old portable superhets

Wheatstone Bridge Receiver -- nice 40m ham band receiver -- its detector is narrow band but has nice bandspread to separate CW signals or SSB

Speaking of upcoming conferences.

Ozarkcon will be held in Branson the weekend of April 1-2, 2016. This conference is for anyone interested in the art of radio.

Besides a build session on Friday, this year the lineup of programs Saturday includes Regens, Phasing receiver construction, and the Raspberry Pi Software Defined Radios. The club will have kits for sale as well. See the website for more information. The hotel is $70/night at the conference.
The Four State QRP group puts this on, and there you will meet many hobbiests who are avid builders in the world of QRP.

Dear Curt,

I am familiar with the WBR from Dave Richards (AA7EE) blog. The
other day I found a PDF copy of the August 2001 QST article by Dan
Wissell, N1BYT.

I will have to look up the Ozark Patrol, and see if I can find the
schematic. It sounds like a good one.

Thank you very much for the Solid State Regen Receiver recommendations.

Sincerely,
SC

If you have a Ham Radio club in your area it may well be worth a visit
as a lot of members will probably have lots of components collected over
the years that they would give you or sell to you cheaply.
I for one have a number of toy boxes, full of components, that I will
never empty in my life time.

That is a good idea.

I am coming to the "homebrew" radio communities after hovering around
the fringes of the DIY Synth communities for a little while. I love to
make noise.

I have also tinkered with small toy robots, controlled by Arduinos.
Actually, it was Arduinos that got me interested in hobby electronics.
They were designed for Artists, Designers, and Hobbyists, and I have a
background in Art. I never thought that I would ever be making
electronics projects of ANY kind, much less building radios.

Thank you very much for your suggestions.

Sincerely,
SC

Suzie, the Ozark Patrol is a good one. The WBR is a little more
difficult to build,
but likewise a proven design. Others include the previously mentioned
F5LVG /
VK3YE high-performance regen, and those of 7EW5JH and VE3LYX
(slug-regen) and
not least a number of others in this group's files. Doubtless other
members will
have further suggestions. (I have more experience with valve/tube regens.)

Manhatten-style construction is well-suited to experimentation. Similarly,
10meg resistors soldered to a copper base can be used as stand-off pillars.

Dear Michael,

Thank you very much for your reply. Dave Richards puts it very
succinctly when he said:

"Like anyone who builds circuits, I have a mental list of things that
I'd like to build which is updated constantly. Some ideas get pushed
to the back of the queue to make way for newer ones, and some stay
pretty close to the front for long enough that eventually opportunity
and desire collide and magically, it gets made."
https://aa7ee.wordpress.com/2011/07/24/the-wbr-a-simple-high-performance-regen-receiver-fo
r-40m-by-n1byt/

I found the Ozark Patrol Kit web page, which included a schematic. As
is my habit, whenever I find a circuit on the Internet, I then go to
YouTube and see if anyone has published a video of the circuit. I
found several videos for the Ozark Patrol, and the kit looks
beautiful. I do not have much experience with kits, but I have put
together a couple of beautiful kits, from Evil Mad Scientist
Laboratories; the "Three Fives" kit, and the "XL741 Discreet Op-Amp"
kit.

Speaking of kits .... I have looked at the MFJ-8100K WORLD BAND SWL
RECEIVER-KIT ($79.95 each)
http://www.mfjenterprises.com/Product.php?productid=MFJ-8100K
I would have to save up for a kit that expensive, but in general, the
reviews for it seem to be very positive.

I also found the PDF article for the WBR, and I am also familiar with
Dave Richards' web pages about it. I think that I might try to build a
WBR after I finish the Desert Ratt 2.

I have seen some valve/tube regens on the Internet, but I am not interested in building anything with vacuum tubes at this point in time. I do not have ANY experience with vacuum tubes, and from what I have heard, they use high voltages, get hot, and can be lethal.

I have asked someone else why they wanted to build vacuum tube circuits, and they replied that the tube circuits (guitar amps in their case) had a nostalgic attraction, among other things. They liked the smell, and the tubes warming up, and they said the sound was better, and so forth. Personally, I do NOT have anything to get nostalgic about with vacuum tubes. They were way before my time. I have seen pictures of them on the Internet. (^_^)

Yes, I am enjoying building circuits with Manhattan Style Construction. There is a similar type of construction called "Muppet Construction" that I would like to try one day.

Manhattan-Ugly-Professional Placement Experimental Technique by Chuck Adams (K7QO).
http://soldersmoke.blogspot.com/2013/04/chuck-adams-muppet-construction.html

I have not had a chance to look at the Files section of this regenrx group, yet. I look forward to getting a chance to see what is in there.

Sincerely,
SC

Dear Neil,

My first regen radio, the Simple Regen Receiver For Beginners, by Charles Kitchin, N1TEV, is as "finished" as it will get? I have a list of things I can do to it for experimental purposes. As far as I know, it performs as advertised, but I do not have any other Shortwave Receiver to compare it to at this time. Hopefully, the Desert Ratt 2 that I am currently working on, will work well enough to have something to compare this first regen to.

I think I have heard some Morse Code on it, but I am not really sure, as I do not know Morse Code at this time. It was high pitched "chirping" that sounded like it might have been VERY fast dots and dashes? I have looked into learning Morse Code, but I have not done anything about actually learning it. I know SOS. (^_^)

I don't think I have heard any SSB? I gather that is what Amateur Radio operators use when they communicate with each other? I am not a "Ham" at this time. I have looked into Ham Radio, but I have not yet done anything about it. I am not too keen on "transmitting" anything to anyone at this time, so I don't think I need a license.

The Short Wave Listening (SWL) hobby is something that I am very interested in, thus my interest in building Shortwave Receivers. These Regen Receivers are supposed to be good radios to build, in order to learn how to build radio receivers. Eventually, I will probably try other types of receivers as well, such as Direct Conversion, and Super Heterodyne receivers. I am really fascinated with Dave Richards' (AA7EE) Sproutie Mk II Regen Receiver which is, in my opinion, a beautiful radio. I aspire to someday build a radio as beautiful (and functional) as the Sproutie.
https://www.youtube.com/watch?v=5TRlfSAswuE

All the best,
SC

Suzie

If you are receiving am signals with that regen most likely it will do cw and ssb. The spectrum around 7 MHz has all these types of signals. If you are tuning around am you may come to a voice that sounds fuzzier. The regen control then needs to be adjusted and with care it can be tuned in. Cw has constant pitch and slow enough to hear a pattern. Maybe curiousity will encourage you to learn it. That signal you described may be radio teletype or another type of signal created from a computer.

Been building regens since my first '30 Lowfer and my '76 BCB rig. Then my first Amateur receiver used for 80m, a straight-out-of-the-Handbook 6SN7 Twinplex. I can honestly say that never once has there been a "re-radiation" issue, even without an RF stage save once....which may or may not have been even me. It was never established, but...

One night during the winter of 1981 I wound some coils for 160m and link coupled the 6SN7 detector to my 40m dipole. It was very early morning, and I fell asleep listening to a QSO. My hand must have swept across the front panel because when I awoke, my regeneration control was full on, maximum. I brought the regeneration back to it's normal threshold position and listened. Nothing...for a few seconds, then the words "Thank You".

Then nothing. No other station was there. The transmission did not identify itself. It was on the frequency from which I was listening to the QSO the night before, it was a side-band signal. I could have chanced upon the end of a qso. Or...I suppose I could have been emitting a couple milliwatt signal on 1850 all night, I don't know.

I have actually tried to get a signal out onto a resonant antenna....and some cases a non resonant non loading antenna...via a properly built and operated regen. I have had hams far and near, good friends who were willing to participate, try their dangdest to copy my receiver at any point beyond the operating desk. Never once.

I had a couple good friends that worked with the A-school guys during WW2, and one of my students was a former "sparks" aboard the USNS Butterfly, that sub that was out on patrol during the Pearl Harbor attack. NR4D is a most interesting guy, 90 years old, and free jumps with the DeLand jump club, but I digress (his kids won't let him jump alone anymore. I think jumping is his response to his sub duty in the 40s!)

Ed says that regens were not an issue because during his tenure the problem child was RADAR in the field. It worked more in favour for the enemy than for the US Navy! Almost always they had to keep it off when submerged because the Japanese had become quite adept at zeroing on their positions by the radar pings. The Navy did have regen sets, many of which were failsafe rigs, but certainly called upon for use. He never heard of the issues assigned to them in these modern times.

But everyone has their own experience, I'll not deny or contradict anyone on the subject or interference from Regens save to say that ANY radio improperly built, operated, and especially both, can be a big bag of worms on many levels. In fact, there was ONE rig that did pose a detectable signal.....a DC rig. Who'da thunk? That LO managed to couple itself nicely to a resonant antenna and was picked up by WD4NFU at a distance of eight miles. Dang! Wish I could get that kinda thing going when intentionally working QRP!!

If Regens cause as much radiative interference as I have heard over the past 44 years....why is QRP then such a danged challenge?? <grin>

Dave: Wireless Age magazine from the 1916-1918 period records the reception of signals sent between decks of the dreadnoughts of the Kaiser's Kriegsmarine from bases along the SE and SW coasts of Great Britain. The sparks made by the make and breaks of the keys aboard the

ships, sent to various other parts of the ships, in particular to the engine rooms, are recorded as being intercepted across the channel via the newly acquired valve regen sets (?). I have heard no latter or subsquent commentary to substantiate the contemporary claim, it may have been buried in obscurity by far more interesting Great War trivia.

Anywhoo....that's my 2d. worth.

Thanks Suzie....I have looked at Dave's stuff and tried making the WBR. I had audio but could never get the regeneration to kick in properly. I took it apart and assembled it three times....maybe a bad part? Pilot error....? I looked at the Desert Rat2 but according to Dave, it doesn't receive cw/ssb well mainly for SWL. I'd like to be able to copy cw on my regen if I build another one. Before getting my ham license in 1972, I built a single tube regen that worked the first time..... in fact, I still have it but needs to be cleaned up a bit. The regen that also caught my interest is the regen using ceramic resonators that Peter Parker came up with. All right, all the best.

Dear Curt,

There seem to be many variables as to which stations this radio receiver picks up. When I was first trying to get the radio working without the oscilloscope being attached to it, the first suggestion I tried was a 100pF capacitor connected to the cathode of the germanium diode and the ground plane. That "fix" pulled in completely different stations than the 1M Ohm resistor which replaced the 100pF capacitor.

Another "experiment" on my list of things to try with this first radio is to replace the 1M Ohm resistor with a 2.2M, 4.7M, or higher Ohm resistor and see what happens. Also, the original article suggests putting a capacitor with a switch on it, in parallel with the air-variable capacitor, in order to switch bands.

I am thinking about making a small circuit board that has sockets that I could plug different components into, that has a switch on it, and so forth, so that I could just solder the small circuit board to the radio, and do all sorts of "experiments" without having to solder/unsolder so many times. I don't know if that kind of idea would work, or not, but I guess the onjly way to find out would be to try it. I have a DIP switch that I could use, and I could certainly etch a small circuit board to take sockets and a DIP switch.

I am currently reading "Experimental Methods in RF Design" by Wes Hayward, et al. I just got the book, and I am still in Chapter One, but there are some good suggestions about "experimenting" with a new radio build. As I have mentioned, I am already working on the layout for the "Desert Ratt 2." EMRFD recommends doing "experiments" with a new radio rather than trying it out briefly, putting it on the shelf, then starting a new project (which is exactly what I have done). So I may have to warm up my 25W SP-23 Weller soldering iron, and do some

more "experiments" on this Simple Regen, before I really get into the DR2.

I have read on the Internet that it is best to tune the Regen knob until it is just oscillating to get a good SSB signal? Whereas, the best results for an AM signal is to get the oscillation to just stop. I am learning how to tune my Regen Radio. It takes practice. I am getting better at it, the more I "practice."

Sincerely,
SC

Dear Neil,

The problem that I had with the Simple Regen Receiver For Beginners is
that I could not get any oscillation without the oscilloscope attached
to the cathode of the germanium diode (D1). At least I was able to get
SOME feedback, eventually. Once I had some feedback, then I could try
to connect different components to D1 to compensate for the 10X scope
probe. Mind you, I am brand new to using an oscilloscope (and
learning how to spell it) so I was really just poking around with a
probe without really knowing what I was doing. I guess I just lucked
out? OMG, I know, right? (^_^)

>
> I looked at the Desert Rat2 but according to Dave, it doesn't receive cw/ssb
> well mainly for SWL. I'd like to be able to copy cw on my regen if I build
> another one.

I read the same thing about the DR2 on Dave's DR2 web page. That does
not stop me from wanting to make one. I also read many horrible
reviews of the Simple Regen Receivers For Beginners, but I built it as
my "first" Regen Receiver because there were just as many positive
reviews of it. The thing that inspires me to go ahead and build a DR2
are the videos that Dave has published on YouTube. I think there is a
lot for me to learn by building a DR2.

It seems there are 10 types of people on the Internet with an opinion
about Regen Receivers: those who Hate them, and those who Love them.
So far, I can put myself in the later category. (^_^)

>

> Neil wa4chq
>

I keep running across plans and kits for vacuum tube Regen Receivers on the Internet, but so far, I have only looked at Solid State designs. I just don't have any experience AT ALL with vacuum tubes. Except for pictures on the Internet, I have never even seen a vacuum tube (or "valve" as the British are fond of saying).

I am currently reading "Experimental Methods in RF Design" by Wes Hayward, et al. I am still in the first chapter. Actually, I am bookmarked at a design for a FET Regen Receiver. I wonder if anyone has built the EMRFD FET Regen Receiver? Do you call it something else? I think I have some J113 N-channel FET transistors in my junk box. If I remember correctly, I got them as a replacement for MPF102 transistors, to build a small audio Amp.

OMG, there is SO much to learn. It boggles my mind. Inductors, coils, toroids, ferrite rods, and other esoteric things are still a big mystery to me. (I am still surprised that the hand-wound coil I made for my first Regen, "worked.") I will be working through EMRFD, as well as building Regen Radio projects, and learning, learning, learning, for the foreseeable future. This is a good hobby: electronics + radio. I just wish I had more time to spend on it, rather than doing it here and there, as time permits. (^_^)

All the Best,
SC

I am familiar with solderless breadboards, and I tried to use one to get the Simple Regen Receiver For Beginners working before I built it on a circuit board. I was NOT able to get it working on the solderless breadboard, but it turned out to be a very good PINCUSHION for components when I built the circuit using Manhattan Style Construction. (^_^)

I have had varied success with solderless breadboards in the two years that I have been an electronics hobbyist. The first one I ever bought was a 340 tie-point breadboard from Radio Shack. It has been a solid performer over the last two years. It was very expensive. I think I paid something like $9.95 for it. However, it is still working great.

The next breadboard I bought was an 830 tie-point breadboard from Adafruit. That breadboard turned out to be BAD. I did not discover how bad it was until I tore off the adhesive backing, and saw cold-shuts in the plastic, which caused a short. The short took me long time to find because I was a raw beginner and I did not suspect the breadboard.

I have also purchased breadboards from Amazon.Com. I thought I was doing good because they were supposed to be from BusBoard Prototypes. It turns out that they were counterfeit boards being sold by an unscrupulous vendor under the name of BusBoard Prototypes. I finally got some real BusBoard Prototype Systems 830 tie-point solderless

breadboards from Mouser. I don't care if I have to pay more. The difference in quality is amazing. Sorry I went on like this, but I will no longer buy cheap solderless breadboards, ever, ever, again. I currently own 6 real BusBoard Prototpe Systems 830 tie-point solderless breadboards, and currently, all of them have circuits on them (mainly synth circuits).

How do I know that the Amazon.Com "BusBoard Prototype" breadboards were counterfeit? When I received the real BusBoard Prototype Systems breadboards from Mouser, I noticed a huge difference between the Mouser breadboards and the Amazon.Com breadboards. The board layouts were different, and the components inserted with a different amount of force. So I wrote an email to the BusBoard Prototype Systems company, and asked them how to identify a "real" BBPS solderless breadboard. They replied with a detailed description of how to spot a counterfeit, and sure enough, the Amazon.Com boards were counterfeit.

How do you like the ready-made jumper wires? I still use custom-cut lengths of 22 AWG Solid Core Hook-up wire with a quarter-inch stripped off each end. I got a really good deal on hook-up wire when the Radio Shack went out of business, and closed their store at The Mall. (^_^)

>

I started off with a CK-1000 Electronics Kit. I still have parts from that kit. Now, I try to order the parts I need for a project from Mouser, DigiKey, or Newark/element14. However, I have purchased old AM/FM radios to see if they have air-variable capacitors in them. I actually found one the other day. I paid $2.00 + tax for it. It was a SoundDesign AM-FM-8-track system from the 1980s. It has all sorts of big components in it, an air-variable capacitor, a ferrite rod, plus other goodies. Most of the other radios have plastic variable capacitors. I found an old TV on the curb the other day and talked my Dad into helping me get it home. I was disappointed that it didn't have too many useful parts, that I can tell. I took it apart outside. I was looking for toroids, and things like that. Nothing like that at all. It did yield a 25 Ohm speaker. I can use that in an audio project. Am I chattering away here, or what? Sorry I am such a chatterbox. (^_^)

>
> Anytime I see a 'kit' of stuff on Amazon at a CHEAP price and I think I
> can use it, I order it while I'm getting something else I need (Often

> up <evil grin>.
>

I used to order electronics from Amazon.Com all the time, but now I'm
getting leery of their stuff. They never have enough information about
the specifications of the components. They are good for books, and
that is all, as far as *I* am concerned. As far as electronics go, I
have had to "return for refund" just about one thing per order. They
are good about refunds, but I would rather that they replace the bad
stuff, not just refund it. Then I have to wait to get another $35
order together (to get free shipping) so I can re-order the thing that
I got a refund for.

I don't shop at E-bay either because my Dad had a bad experience with
them, several years ago, and he is the one with the credit card, and
he will never do anything with PayPal ever again. What can one do?
(^_^)

>

>

I have also been surprised at how fast things ordered from China
through Amazon.Com arrive in my mailbox. I have heard that their
Government subsidizes the mail? Anyway, here again, when I think I am
getting a "good" deal from a Chinese seller on Amazon.Com, I have been
disappointed in the overall quality of the components, compared to
similar components ordered through Mouser, DigiKey, or
Newark/element14. I think this has to do with the poor specifications
of components at Amazon.Com? For example, the leads on components from
China/Amazon.Com are extremely thin, and the leads from similar
components from Mouser are much thicker. It makes a big difference
when sticking them in solderless breadboards, don't you think?

I know that I am just a beginner at all this, but I try to pay attention to EVERYTHING I do. I don't make a lot of money working part-time, so I try to be VERY careful with the money that I do make. I wish the job market were better, and that there were more, better-paying jobs available, but there aren't, and it isn't, so why am I crying about it?

I am having fun with Hobby Electronics+Radio. I like making things. I still live with my parents, so I don't have to pay rent/utilities, or buy food, or any of the tons of other things that are required to live on my own. I get along well with them, and they get along well with me. Yay !!! (^_^)

Best Regards,
SC

Suzie, you are doing it all right - keep experimenting with the same design until
you are sure it's working as well as it should - or until you feel you have learnt enough
to move on :-) I remain curious to know whether R3 worked better as 1k or 100k. I only tried it with 100k, but felt uneasy with the open "floating diode".

Discarded electronic equipment can yield lots of components, which are usually
of good quality. It is fiddly, but cheap. If you can liaise with local hams, they will
doubtless be willing to help.

Solderless breadboards have their quirks, as you have discovered. They are more difficult to use for radio-frequency designs because of unwanted capacitance effects. In a regen, the regenerative detector's components often need to be grounded at the same point, or close together. The Manhatten pads you have been using are better suited. You can cut your own out of old bits of circuit board.

The MFJ-8100K you refer to is a good design, with various mods and clones. You could build it with components you already have to hand and a few extras
much cheaper than buying the kit. Search online for MFJ-8100, Clone MFJ, Ten Tec 1253, Veronics VEC-102K and similar.

Michael

Dear Michael,

Thank you for your words of encouragement. (^_^) As you know, I used my oscilloscope to troubleshoot the Simple Regen Radio For Beginners after I first built it, and it didn't work. I am continuing to try and find some information about that. I am trying to learn how to use my new oscilloscope, and I think that this radio might be a good subject for testing.

I will try to get my soldering iron out, hooked-up, and melting solder in the next few days. I will certainly trade out R3 from 1K to 100K and see what happens. . It seems like a huge difference between them, like two orders of magnitude? Is that right? It won't blow up the circuit, will it?

There is a Goodwill Outlet several miles away from where I live. This is a place where they take stuff that doesn't sell at the regular Goodwill Retail Stores, at regular Goodwill prices. At the Outlet, they sell stuff by weight. For electronics, they have a list with basic prices on it. I recently found a SoundDesign AM/FM/8-track deck for $2.00+tax, that yielded an air-variable capacitor, a ferrite rod,

and all sorts of other big radio components. I don't think I have ever seen an 8-track whatever (tape/disk/cartridge/?). It is from the 1980s. They also sell small computer printers for $2 each, and the larger computer printers for $5 each. I think that might be worth it for the stepper motors alone? I havfe to be very careful about how much stuff I bring home because I don't have much space, and I am not allowed to fill up the trash bin so that my Dad doesn't have enough room to put the trash.

I found an old TV by the curb the other day, and my Dad helped me get it home. Sadly, it did not yield too much. I was looking for an HC-33 crystal of some kind, and maybe some toroids, but this set just didn't have any "goodies" as far as I can tell. But, then again, what do I know? I put all the circuit boards in a box, so I can salvage components from them in the future.

I have picked up a couple of tiny (5-inch diagonal) B&W TVs at the Goodwill for $3.00 each. I don't know why I bought them? Well, they are cute for one thing. One of them actually picks up some stray radio signals, here and there. Also, I remember one synth artist who used an old B&W TV to make an oscilloscope for one of his synths. The waveform moved to the synth output. Maybe one day I'll know enough to try something like that? I justified the purchases because I don't know how much longer these old TVs will be available? For the most part, the Goodwill no longer accepts old tube TVs for donations. So I guess most of them are going to the landfill?

I don't think I'm going to waste my time with any more old TVs. I'm glad I was able to get the curb TV taken apart without getting shocked by an old capacitor, or whatever. I am still disappointed by that "find."

I cut the pads out of copper-clad board with a jewelers saw frame and a 2/0 saw blade. First, I layout the lines on the board with a fine-tip Sharpie, then I cut along the lines.

I actually found out how to access the files section of regenrx and regenrx2 the other day. I had to get a Yahoo account to do it. I am subscribed to this list with a non-Yahoo account, so I didn't have access to the files section. But now I do. I do remember seeing a file for the MFJ-8100 Clone. I will look for it again. It would be really nice to be able to build it myself, for less than the cost of a kit. I would rather do it like that anyway. (^_^)

Good to hear from you again, Michael. I appreciate your help.

Sincerely,
SC

The Desert Rat receiver doesn't seem to receive SSB stations very well. The tank circuit is at the collector of the Q-Multiplier BJT. Shifting internal capacitanes with the modulation of the SSB signal detunes the tank circuit, causing a warbled sound of the detected SSB signal. To cure this problem, substitute the general purpose BJT of the Q-Multiplier with an RF transistor which has much less internal capacitances.

Thanks for the great insight. How can you tell with a regen when you are picking up an AM vs SSB signal? Can you monitor with an ammeter when you are getting closer to oscillation meaning the CW detection mode vs the AM or SSB area of regeneration.
Thanks Dan W3DKY

Dear dawmast,

Thank you very much for this information.

I am currently working on the Manhattan Style Construction layout for the
DR2 circuit, based on the work done by Dave Richards (AA7EE) at:
https://aa7ee.wordpress.com/2013/05/11/the-na5n-desert-ratt-2-regen/

So far, I have redrawn his schematic (posted on the above web page) to
become more familiar with the circuit, and to try and see what
modifications he made to it, from the original schematic by Paul Harden (
NA5N), seen at: http://www.aoc.nrao.edu/~pharden/hobby/DR2.pdf. There is
also a description of how the circuit works, located at:
http://www.aoc.nrao.edu/~pharden/hobby/DR2descr.pdf

This is what I am working from:

As far as I know, that is an accurate reproduction of Dave Richards
schematic of his version of the Desert Ratt 2.

My next step was to trade actual component outlines for the schematic
symbols, thus:

I have missed a few schematic symbols in the above drawing, but all of them
will eventually be reworked.

The next thing I do is to start making the Manhattan Style Construction
layout by adding pads to the drawing.

This is a work-in-progress, and is far from being finished. I do all the drawing using a graphics program called Kolourpaint, which is VERY easy to use, and has all the tools I need.

As I work on the layout, from time to time I will check my work against the schematic, to make sure that I have not strayed too far from the actual circuit. However, I will be pushing and pulling pads and components to make things fit together better, and to get various knobs up to the front panel, and so forth. I used this technique successfully with my very first regen radio, "A Simple Regen Receiver For Beginners" by Charles Kitchin, (N1TEV).

It takes a long time to do all this drawing, and this technique is probably NOT for everyone, but *I* enjoy drawing, and as I work on the drawings, I slowly become familiar with the circuit. At first it seems very complex to me. But as I draw, it becomes less complex.

Greetings,
SC

Hi Dan,

When you tune through an AM signal with the detector oscillating you will hear the AM carrier as a tone that decreases in pitch as you tune through from one side to the other. The tone will decrease in pitch until it disappears - zero beat. Continue tuning in the same direction and the pitch becomes audible again but increases in pitch as you tune farther from the carrier. It is exactly the same as having the BFO on in your superhet while tuning through an AM station.

An SSB signal does not radiate a carrier. If you turn your superhet BFO off or your regen detector not oscillating then SSB will *never* be intelligilble but will always sound like Donald Duck mumbling and grumbling. To recover SSB (or CW) you must have the BFO on in your superhet on or the regen detector must be oscillating.

With no incoming signal but only "noise" in your receiver you will hear the noise "change" when the the regen detector goes in and out of oscillation as you increase and decrease the feedback. Increase the feedback to get into oscillation

73,

Bill KU8H

Thanks Bill,

I never understood most of what you just told me, especially zero beat.
Are you saying that if I want to pickup AM the detector has to be just on
the verge of oscillation to hear the audio, and if it is oscillating that I
will here a tone only which is the carrier. Which means that the crystal
diode did not demodulate the signal yet. I assume that what you told me is
true for crystal sets as well as a 6sn7 regen. Can one monitor the actual
moment when the tube or diode goes into oscillation and when you are
creeping up on it. Can a micro ammeter measure the grid or plate activity
on the 6sn7 or a dip in resonance or feedback on the tanks circuit?
Thanks so much I think I see the light or at least the dawn.

Date: 2016-02-07 16:04:58 UTC
From: Prof. Arnaldo Coro Antich
Topic: 25800 Message: 25800

Hola amigo Cris:

Nice to see the schematic of the ECH81 front end...
It may be improved a little bit by using a dual tuned bandpass
input RF filter.... How do you regulate the operating point
of the triode to move it into oscillation as required for CW and
Single Side Band modes. By the way, it will also pick up the
digital modes like PSK31....!!!
The ex Soviet Union vacuum tube equivalent of the ECH81
I think that is the 6I??? P... I like in India... and it was used
in the famous R250 series of professional communications
receivers...
Have you seen the information about the ZL2JJ Regenerative
Receiver ?....
I have the complete files...although it uses very old vacuum tubes
the design can be adapted to more modern types, and the
mechanical layout is something to be studied for best shielding
and ruggedness ....
Congratulations for helping all of us regenerative radios enthusiasts
to build better radios with whatever parts we have available...
Finally a question not only for you but also to everyone
on our glowbugs and regennx internet lists:
QUESTION :
Have you compared side by side your best
vacuum tubes regenerative receiver with your best solid state
(junction transistors or FET or MOSFET) regenerative receiver?

I have yet to do that test in a ¨scientific¨ and properly instrumented
test condition... but from my more than 50 years of experience
on this subject of regenerative radios, so far not one solid state
design has matched even by second or third choices of vacuum tube
sets, and never matched the top best design !!!
Keep up to good work
73 and DX
Arnie Coro
CO2KK
Host of Dxers Unlimited radio hobby program

Hi, Prof. I'm always interested in other peoples regens, and I would like to see the ZL2JJ design you mentioned. I have plenty of old tubes, including a couple of WD-11's, but I would probably use 864's, since I have several of them. It would be great if you could post the schematic, now that we can include graphics with our email.

Leonard

I also prefer a maximum B PLUS voltage of no more than 140 volts
The electrolytic filter capacitors are also recycled from the CFL
circuit boards.. they are 22 mfd at 250 volts... so just use two or three
in parallel for the PI capacitor-resistor-capacitor power supply
smoothing filter....

Generally you have a cap from input to the volume control.

ALSO! Generally you have some cap across the diodes to keep switching pops from coming thru radio receiver. I would use 0.01 uFd.

Using Thunderbird (as a struggling new convert...) I find that
schematics are easily extracted and saved : right-click, then save-image-as.

Michael

Dear Phil KO6BB,

Thank you very much for all of the information about parts.

When I was hanging around the fringes of the DIY Synth communities I ran across a list of components that were most often used by syth builders, and that they usually included in an order to a parts distributor. Here is a *small* part of that list:

Electrolytic Capacitor 25v 100uF 20%
Electrolytic Capacitor 35v 47uF 20%
Electrolytic Capacitor 25v 4.7uF 20%
Electrolytic Capacitor 35v 1uF 20%
Ceramic Capacitor 470pF 50V 10%
Ceramic Capacitor 1000pF 50v 10%
Ceramic Capacitor 4700pF 50v 10%
Ceramic Capacitor 0.01uF 50V 10%
Ceramic Capacitor 0.047uF 50V 10%
Ceramic Capacitor 0.1uF 50v 10%
Ceramic Capacitor 0.47uF 50v 10%

You can see that there is a pattern of values in that list. Do you have a similar list of components that you always keep on hand for building solid state radios? When I order parts from a distributor, I try to order at least 10 of each part, and I get a price break. However, I can't always do that. It depends on how much each part costs.

How about tolerances? I think that Mr. Kitchin's Simple Regen Radio For Beginners did not have any requirements for tolerances? If you were starting to buy parts to build "archive quality" solid state radios, would you stick to 1% tolerances? Although I am almost certain that there are other tolerances for components, I am familiar with 1%, 5%, 10%, and 20%.

I have read that the wire-wound resistors are not good for building radios because they have a certain amount of inductance, due to the coil made by the wire. So non-inductive resistors are probably a good idea, overall?

I am slowly learning about ordering parts. I still make mistakes, mainly due to not reading the specifications closely enough. Things that I get wrong, more often than not, are the lengths of the leads. I like to get leads that are long and not too thin (thicker leads go into a breadboard better than really thin leads). It is a good thing that it takes me so long to draw a circuit and a layout because it usually takes me weeks to find parts for a project.

I remain leery of Amazon.Com because lately, they have gotten much worse at packing stuff. I found my SDS1052DL Siglent oscilloscope at Amazon.Com, and ordered it alone. The scope arrived okay, but they threw a fragile item from a separate order in the box with the scope, and it arrived broken. I had to return it for a refund. The thing is, I ordered the fragile item with two other light-weight items in a completely separate order from the scope, and all of those items should have been shipped together, but Amazon.Com mixed and matched shipments, and just threw the fragile item loosely in the box with a heavy oscilloscope box. <sigh> That is just one of many returns I have had to make recently. If it only happened every once in a while, fine, I could probably deal with it, but when I have to return something from almost every order, it gets old really quickly. I am going to boycott Amazon.Com electronics parts for awhile. I am only going to use them for books from now on. Even so, the last thing I ordered from Amazon.Com was a book and an electronics gadget. They arrived on-time, and the box was in good shape, and the book inside the box was okay, and the electronic gadget was undamaged, but the electronic gadget did NOT work. It was Dead-On-Arrival. So I had to return it for refund. So I'm just not going to order any more electronics parts, or gadgets, or equipment from Amazon.Com. I am glad to hear that you have had good experiences with that company. I sure wish I could say the same thing. Sorry for going on like that.

I will comment more on your post.

I can highly recommend the solderless breadboards from the BusBoard Prototype Systems company. http://www.busboard.com/
In this case, I have had experience with cheap breadboards from other vendors, and quality breadboards from a reputable vendor, and I will NEVER go back to the cheap breadboards, ever again. It is worth the few extra dollars to get quality solderless breadboards. Likewise, I have purchased some of their stripboards and prototyping boards (perfboard), and the quality of those is also head and shoulders above the cheap varieties. I am really starting to appreciate quality

materials and parts. Even if I have to wait an extra month or so to earn the money for quality, I will do it because to me, it is worth it. I really didn't understand it when I first started out (and I still consider myself a beginner), but I am quickly becoming an evangelist for using quality parts, and eschewing cheap, poor-quality parts. I am sure that more experienced radio builders can probably make anything work.

>

I go to Jameco and look at their parts when I am shopping for components, but what they don't seem to understand is that while I have their catalog open in a browser Tab, I also have Tabs open at Newark/element14, DigiKey, and Mouser. Usually, Jameco loses my order because their prices aren't low enough, or I they want to ship a generic part (Manufacturer? Major Brands? Jameco ValuePro? what are those?). I have ordered from Newark/element14 before, and gotten good parts, but my Dad didn't like the way they billed his credit card, so I stay away from them, for the most part, unless they have the parts at the best price, which is not always the case. Likewise, DigiKey has not been able to beat Mouser at lowest prices. Often, Mouser offers a price-break at ordering 10 parts, and DigiKey's price-break starts at 25 parts. How about that? So I have mainly been using Mouser when I order parts. I still do comparison shopping, with Tabs open for each distributor. I have also looked at sites like OctoPart. There are other Parts Search Engines as well. I just like my browser Tabs approach. It is always an education to search for electronics components and parts.

It sounds like you have some really good experience. There are no longer any TV shops around here that I know of.

>
> So I sort of 'need' a stock of basic parts
> like resistors, capacitors, common transistors etc.
>

That is what I am trying to figure out. I think that once I have built a few solid state Regen Radios, that I will ahve a better idea of which "common" parts to have on hand.

>

My first CK-1000 Parts Kit had all sorts of components that I have never used. Other parts ran out quickly, but believe it or not, Radio Shack did not carry the same parts as was in their CK-1000 kit. So they lost my business when I had to re-order the parts used most often from other distributors. I don't know, but I think I got into the Electronics hobby too late. I think Radio Shack closed about a year or so after I got into electronics. The RS at The Mall was really just a cell-phone store. None of the sales associates knew anything about what I was looking for when I went in to buy a component or two for a project. I did buy about $30 worth of stuff when the store closed, and it was about $300 worth of stuff if I had paid full price for it. I could have done better if I had known what to look for. I did get several spools of wire, which is something that I use a lot of. $9 spools of hook-up wire were going for $1. Solid core copper hook-up wire and copper stranded wire as well. I also got several spools of 24 AWG stranded copper speaker wire.

I have seen the JoeKnowsElectronics kits and I have passed them over. Thank you for your review, but I am currently boycotting Amazon.Com for all electronics components and gadgets. If I can find the brand from another source, I may consider trying it?

>

> "Add-On" items.
[snipped]
>

I think that if I continue with the electronics hobby for awhile longer, then I will eventually build up a pretty good "junk box." It took me over three months to save up for the oscilloscope I bought, so I am already vested in this hobby for the time being. I got the oscilloscope for building synths, then got sidetracked by radios. I can use the scope for both.

>
> Now to be perfectly honest, there were a couple things from Amazon that
> I was less than happy with (but not enough to keep me from using Amazon
> again, I've just gotten more careful in what I order after reviews etc).

I must admit that I still use Amazon.Com for the "reviews" especially for books. But I am using my local Public Library more these days. Many books in a subject area repeat much of the same information, over and over, especially Beginner books.

>
> What comes to mind is. . .
> 1. When I designed/built my 7 tube + rect regen (actually 5 tubes

>

I bought rechargeable 9V batteries and a charger from Amazon.Com, and they were okay. Tenergy was the brand name. Low Self Discharge batteries. They power my DMM, robots, synths, radio, and so forth.

>
> 3. I ordered a package of 80 colored LEDs for $2.80 from an Amazon
[snipped]
> it", she didn't want her accounting to get messed up (I let her do the

>

The one thing I got from China, ordered through Amazon.Com, arrived in about 10 days from the order date, but it didn't work as advertised. The company refunded my money, and told me to toss the item in the trash bin, which I did. Trash is trash. Here again, I was going for "cheap" instead of "quality". I order the quality part next, an was not disappointed. Yeah, it cost a few dollars more, but it worked, and it is still working.

>
> But outside of those three things, I can't really think of any thing
> I've received from Amazon that wasn't as promised, or had problems..

>

Well, you've gotten an eyeful of my bad experiences with Amazon.Com in this post. Except for books, they have lost me as a customer. BTW, I am really enjoying the book that I got from them: "Experimental Methods in RF Design" by Wes Hayward, et al.

>
> To answer your question on the jumper wires. I like them very much, the

Thank you very much for that review. I have seen various packages for jumper wires for breadboards, but I have not bought any, yet.

>
> One of the bigger things I DID buy when the local RS store was closing

I have an old power supply from a computer that I am considering turning into a bench power supply. The more I make stuff, the more I am finding out just how handy it would be to have such a piece of equipment. I have looked at several tutorials on how to make a DIY PS from a computer PS. I think I can do it, if I keep it simple.

>
> But yes, I think the jumpers are good quality, and I don't have to worry

>

So far, I have had some wire ends break off in the breadboard holes, but I have been able to get them out using the edge of an X-Acto knife

blade. There may come a day when one breaks off too far inside for me
to get it? It hasn't happened yet, knock-on-wood.

>

Those days are long gone, as far as I know. There aren't even any more
computer shops around here. If a computer breaks around here, people
just throw them away and buy a new one. I have several old computers
that I have pulled out of the trash bins in my neighborhood (picture
me in a do-rag, jeans, sneakers, and a sweatshirt, dumpster diving -
LOL). One day I will take them apart and scavenge components from
them. That day may come sooner than I expect because my Dad said the
basement was getting to cluttered with junk, and I'd better start
thinking of what to do with some of it. I was surprised when he helped
me pick-up an old TV that was on the curb in the neighborhood. But I
took that apart as soon as we got it home, boxed the circuit boards,
and threw away the rest of it. Actually, it IS getting cluttered down
here. I really DO need to clean it up. (^_^)

>
> It's good that you're still living with your parents and have a good

>

I agree. I have no complaints at all. To live on my own, I would need
to have three or four part-time jobs, so that is totally
out-of-the-question. Then I really wouldn't have time for any
electronics+radio hobbies, and I would just barely be able to make
ends meet. I don't even have my own car. I have done the arithmetic.

>
> I've NEVER bought anything from eBay as I remember the early days when

What is the saying? Once bit, twice shy. That is my Dad. Nothing from
eBay at all, no matter what. For me, eBay does not exist. I don't even
look at stuff there, no matter what. What good would that do me?

>

Yeah, well, I hope I can live to be 60 years old. It seems like such a long time from now. I have no idea what the future is going to be like? I will enjoy my hobbies as long as I can. It is fun to learn new things.

From: wa4chq@...
Topic: 25818 Message: 25818

Hi all... I tried building the WBR last year and had partial success with it. After 3 rebuilds and no luck I decided to but the project on the back burner. My space is limited these days for 'brewing so I may go for long periods without lighting up the soldering iron. Lately I've been hit with the regen bug again. I've looked at some of the solid state projects here and on you tube. I kept going back to Joe's Reflex Regen. It sounded really nice and and it covers 80 and 40m with a flick of a switch. And Joe sounded like a really nice guy, he would be the Elmer I never had. Well I just learned that Joe, K8LKC is a SK...he passed away the 16th of January. I didn't know Joe. I only found him when looking at the regen rcvrs on Youtube. So, I think now more then ever, I will build "Joe's Reflex Regen".

Very interesting story. It does have me curious how Joe's regen compares with the recent Ozark Patrol (schematic at 4state qrp, I did mine homebrew). The OP is a very nice SWL style receiver that copies AM signals wonderfully (with much less fading than my first portable superhet) and can be adjusted to copy some CW and SSB (if you carefully look for it)

Also, I had good success somehow with the WBR. Its a wonderful 40m ham band receiver. I had all but the varactor diodes - these were sampled from someone like Skyworks - I put the tiny diodes onto a little test board that had appropriately spaced pads. if you have one started, I would not throw it away.

Topic: 25821 Message: 25821

Hola amigo !
Sure... great idea... and easy to put in practice...
My projects now are aiming at helping the young and not so young
newcomers to amateur radio here in Cuba be able to start listening
to 40 meters ...
Why 40 meters ? Because due to the daytime propagation characteristics
it covers our whole archipelago with very good
signals .... and at night you can pick up Dx stations too.
The radios must be ¨barebones¨ because electronic components
are not sold at any stores... so we must recycle parts from
equipment retired from service because of old age, breakdowns
and even struck by lightning !!! Yes, I have desoldered parts
that were part of a radio struck by a nearby lightning... not a direct
hit of course, but it left the radio dead for all practical purposes
because of the many IC's that were damaged !!!
A regenerodyne is the proper phase two of anyone wanting to
build her or his own receiver... I always start with a regenerative
that picks up signals on the AM broadcast band, so that the builder
will be attracted further by the fact that the radio built does
¨work¨ and audio comes out of a loudspeaker...
YES, a loudspeaker , better than headphones, because if makes
the project more attractive.
My vacuum tubes circuits designs are tried and tested, and I
include for every part a span of values that can be used and the
radio will still work...
For example the RC resistor capacitor circuit at the grid of the
regenerative detector will tolerate large deviations in values
from the optimum ones.... My preference for general reception
is to go for a small value capacitor , less than 100 picofarads
and a resistor at least 1 megaOhm... but the radio will work
with 50 pF and 2,2 megaOHm etc etc...
The favorite regenerative detector is the Hartley.... with a pentode
using screen grid control of the regeneration...
If you need any advice to start building your own regenerative
receiver, just send an email amigo...
No doubt that vacuum tubes regenerative are mucho , mucho more
better than solid state versions !!!!
Some of my regenerative detectors have started to receive
with less than 12 volts applied to the plate of the pentode...
but running around 24 to 50 volts or so is better...
I divide the project into several ¨modules¨ ... and build them
individually, then test them, and then do like at the aircraft
factories... integrate the modules into the receiver....
The typical regenerative with a Hartley detector uses

one 6AK5/5654 or Soviet 6ZHE1P pentode , and an audio
module built using a triode/pentode that comes in a single
glass envelope... The power supply module has three outputs
6.3 volts AC, 6.0 volts regulated DC for the regenerative
detector tube filaments, and the B plus that provides 140
volts DC for the audio tubes, and 36 volts regulated for the
detector plate and screen....
Winding the coils for the detector is a lot of fun... especially
because you must optimize the cathode tap on the coil...
in general to start testing , wind 20 turns of enamel wire
about no. 18 or no.20 on a 25 mm diameter plastic white
PVC tube... the antenna link is separated from the main coil
by about 5 millimeters (this is for the first test, because later
you will want to build a variocoupler to bring the signal from
the antenna into the grid tuned circuit...
The great attraction of this project is that it will practically
always ¨work¨ and there are very few chances of spoiling
parts (like what happens with solid state components
irreversibly damaged by just a little mistake)
Start by studying the circuit , then gather the parts, and
begin by assembling the power supply... testing it, and then
proceed with the audio amplifier module...
The RF module is the last to be built !!!

Hi 2 all, this is my first post in this group. :)
I found this regen receiver with ech83 tube. I'm interesting how much is good this regulation of feedback with voltage on grid(s)? What are the experiences?

Thanks!

25825. Re: ECH83 Regen

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-12 01:14:50 UTC
From: les.au49@...
Topic: 25822 Message: 25825

Hello Rile, Welcome to the regenerative receivers group! As I understand your question, you want to know how effectively the screen grid voltage controls the regeneration in your radio.

I built a detector somewhat like yours, but using the Hartley circuit (where the cathode is connected to a tap, part-way up the coil. I followed Prof. Coro's recommendation for this circuit, (using a 6AK5 detector and B+ supply of +36 volts). He wrote that this circuit worked very well indeed, and basing my answer on that AND my experience with the circuit I built I would say, "Very well indeed". Regeneration is very smooth. The receiver is very sensitive. In my set, the detector is most sensitive when the screen grid voltage is between 9 and 12 volts.

HOWEVER, David Newkirk wrote that the pentode + Hartley circuit is superior to the pentode + Armstrong (tickler) circuit, because the screen grid acts as a shield for the anode. His point is that the plate circuit (in a perfect circuit) would have NO RF signal present. There is a little, of course, or the regeneration in your circuit wouldn't work.

So - to answer your question a second time - controlling the regeneration by varying the screen grid voltage works very well. I suggest you go back thru the archives and search for postings by Arnie Coro, with keywords 6AK5 and pentode detector.

73 from Australia!
Les

25826. Re: [regenrx] Re: ECH83 Regen and try testing regenerative detectors with frame grid tubes

Dear amigos Les, Rile and the other regenrx list members:
I want to test the same Hartley circuit using a frame grid
pentode... That is going to be a very interesting experiment
with the EF183, 6EH7, or EF184 and similar tube types....If any of you
cantry out this type of very high gain pentodes developed for
use by TV sets IF amplifiers... please go ahead and tell us
the results... My initial analysis is that the EF184 that is not
a variable mu tube would work better....
EF183

25828. RE: [regenrx] RE: The EF184 Is worth trying as a Hartley regenerative detector with screen grid regeneration control !!!]

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-12 02:18:15 UTC
From: Hubert Miller
Topic: 25828 Message: 25828

Arnie, a couple years back, rob (in Japan) tried a number of substitute tubes in his Knight Spanmaster regen, which has a 6BZ6 detector, no RF.

I don’t think he tried a 6EH7, but of all the tubes he tried, if i recall, the 6CB6 was very good, or maybe even best. So i suspect a higher transconductance

tube is maybe not the preferable way to go.

I have wondered if the 6EH7 might work well as a very low B+ regen detector. Maybe the transconductance in normal operation is so high that it would

even function with lowered filament voltage and plate voltage.

Many many years ago, when i was still in high school, i had a Lafayette HE-10/ KT-200 receiver, and i liked to wake up late at night and try for So. American

60 and 49 meter stations, especially looking for stations playing la musica andina, me gustaba tanto oir los huaynos y pasillos, and i replaced the 6BA6 RF in

the radio with a socket adapter and a 6EH7. That is one hot RF tube! I think i got the idea from an article in QST circa early 1960s. I think the article also

the 6EJ7 in mixer use. (The antenna was long and high, and this was before computer noise, BUT the antenna was oriented so its maximum reception

was from Colombia and Venezuela as well as the South Pacific.)

I have a Hallicrafters S-107 which has a rather unique RF ciruit: no RF stage, and the MIXER and IFs are 6BA6. (it did surprise me that the mixer was not

a sharp cutoff tube, more like a 6AU6..) I have been thinking it might be fun sometime to make a plug-in adapter and try a 6EJ7 in the mixer slot. I kind

of like that the circuit does not use an RF, but does use a mixer of lower noise than the usual 6BE6.

-Hue Miller

25829. Re: a first regenerative radio power supply advice

Yahoo group: regenrx (2016 — 2017)

From: Prof. Arnaldo Coro Antich
Topic: 25829 Message: 25829

Hola amigo;
That power transformer will be OK ! There will be enough current
to run a typical vacuum tubes regenerative receiver with one
RF amplifier stage , the regenerative detector and the audio
amplifier module made with a triode-pentode tube or separate
tubes, one triode, and one output pentode...
The regulated DC supply for the filaments will be also OK...
I normally feed the filaments of the regenerative detector with
the regulated DC supply, and if I have enough current available
I also provide regulated DC to the audio tubes...
Again the audio module in a typical design may be a triode-pentode
in the same glass envelope like the ECL82 / 6BM8... or similar
and another alternative (that I often use too) may be implemented
with a triode like 6C4/EC92, or old 6C5 and the output audio tube
6V6/6AQ5/EL84....
The Faraday shield is nice to have, but not essential ....
Good luck with the drawing of the schematics !!!!

25830. Armstrong Regeneration and Screen-Voltage Detector Control

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-12 17:25:27 UTC
From: J Ed
Topic: 25830 Message: 25830

Hello all,

I'm contemplating another regenerative receiver design to make soon. Here's a link to a schematic that will be similar to my detector stage. I intend to control the oscillation with voltage to the screen.

http://www.angelfire.com/electronic/funwithtubes/Regen_det.html

I intend to use an Armstrong-type feedback mechanism as shown. One thing I intend to do differently is to have plug-in coils with a fixed capacitance across each one. The fixed capacitance has been calculated in order to reduce the tuning range. Using a small variable capacitance of 8-40 pF, I'll be able to realize ranges of 500-750 KHz instead of several MHz per coil.

Is there a reliable way to determine the number of turns on the tickler coil? I've built many regenerative detectors and have had problems making some of them oscillate. It's possible that I didn't have a strong enough tickler winding, therefore not enough fed back signal to make the thing oscillate.

Also, I have had problems with this particular design. As you increase the pot on the screen, the voltage increases and the tube conducts more. There's a point at which the tube conducts the most and I hear the strongest signal output. After that, any further advancement on the control lessens the signal. It's because the 100K resistor in the plate circuit causes the plate voltage to drop, reducing its effectiveness while increasing screen current. I'm not sure if there's anything that can be done about it, though.

I would appreciate shared experience with these problems. My intended tubes are 6EH7 and 12AU7 or something similar. I could also use 6SN7 and some octal pentode, too. I'm pretty sure I want to use 9 pin tubes, though.

Ed AE7TE

This should be capable of yielding a voltage of 140-160 V DC but the current ratings are lower than you recommend. I don’t know if the transformer has a Faraday shield between the primary and secondary but it is recommended for tube circuits. Is it okay? The filter choke I was able to locate is 7H, 150 mA. Is the lower inductance okay? For the 6.3V DC regulated filament supply for the detector I am planning on using a 12.6 VAC secondary transformer, a bridge rectifier (followed by R-C filtering) and a voltage regulator IC to get 6.3 VDC. Once these components are decided, I will draw the circuit and send it to you for comment.

To build the power supply with 140 V for the audio tube(s) and a regulated 36 V for the detector does on need a transformer with appropriate taps or does one obtain it from the same tap with voltage dropping resistors? Do you use transistors or ICs for the voltage regulators (both for 36 V and 6.3 V)?

I have built both regenerative and superhet radios (vacuum tube and transistor) for the AM (MW) band - essentially following the circuits designed by others. The vacuum tube radios I built have used battery tubes, both miniature and subminiature tubes. I have also built recently a solid state region for SW. However, I am not happy with the results of this SW regen (although it receives broadcasts from Havana, Cuba quite well!). If you can provide advice on building a vacuum tube regen for SW that works well, I would greatly appreciate it. I am not a radio ham but enjoy building and listening. It would be great if I could listen to SSB transmissions.

25832. A few comments about your message to the list explaining the use of an Armstrong regenerative

Yahoo group: regenrx (2016 — 2017)

From: Prof. Arnaldo Coro Antich
Topic: 25832 Message: 25832

Dear amigo Ed---
Please notice that you have a fixed 200 pF capacitor to return
to ground the tickler coil !!!
My advice is to try to use instead an air spaced variable capacitor
of around 300 picofarads if your radio is for the AM broadcast band.
Then you will have not one but TWO regeneration controls... this
new variable capacitor and the already existing 100 kiloohms
screen grid voltage control.
I also suggest replacing the 100 kiloohms fixed plate resistor with
a high inductance choke.... The value of that part may be as
high as 300 Henry , or as low as 10 Henry.... and in both cases
in my opinion it is a better option than a fixed carbon load resistor
for the plate circuit.
That's about the Armstrong regenerative circuit...
BUT, I prefer to use the same pentode regenerative detector
as a Hartley oscillator circuit... using coils that have three terminals
one to ground, one a tap to the cathode of the tube, and the upper
end going to the number one grid .
The Hartley when properly set up (experimenting with the position
of the cathode tap) in my opinion provides a very smooth regeneration
by the variation of the screen grid voltage... For example using the
triode section of an ECH83 tube, a very nice performance is
achieved with just 36 volts on the plate and the screen grid voltage
moving from 3 to 15 volts....
If you need more information about the values used by this
circuit , the Hartley regenerative with a pentode tube,just
send an e'mail
73 and DX
Arnie Coro
CO2KK

Hello all,

I'm contemplating another regenerative receiver design to make soon.
Here's a link to a schematic that will be similar to my detector
stage. I intend to control the oscillation with voltage to the screen.

http://www.angelfire.com/electronic/funwithtubes/Regen_det.html

I intend to use an Armstrong-type feedback mechanism as shown. One
thing I intend to do differently is to have plug-in coils with a fixed
capacitance across each one. The fixed capacitance has been calculated
in order to reduce the tuning range. Using a small variable
capacitance of 8-40 pF, I'll be able to realize ranges of 500-750 KHz
instead of several MHz per coil.

Is there a reliable way to determine the number of turns on the tickler coil? I've built many regenerative detectors and have had problems making some of them oscillate. It's possible that I didn't have a strong enough tickler winding, therefore not enough fed back signal to make the thing oscillate.

Also, I have had problems with this particular design. As you increase the pot on the screen, the voltage increases and the tube conducts more. There's a point at which the tube conducts the most and I hear the strongest signal output. After that, any further advancement on the control lessens the signal. It's because the 100K resistor in the plate circuit causes the plate voltage to drop, reducing its effectiveness while increasing screen current. I'm not sure if there's anything that can be done about it, though.

I would appreciate shared experience with these problems. My intended tubes are 6EH7 and 12AU7 or something similar. I could also use 6SN7 and some octal pentode, too. I'm pretty sure I want to use 9 pin tubes, though.

Arnie,

Thanks for the reply. I did use a Hartley once in my last serious Regen project. It was a 12AT7 and 12AU7, with the first tube as an RF amp / Detector and the second tube as a two-stage audio amp. It worked well but didn't like to oscillate much on the higher bands. I still picked up AM stations at a very high frequency but I never bothered checking how high it went.

The whole thing was powered by a 24 volt power pack. I want to use a real B+ for my next regen (real meaning 300-ish volts).

If I had a spare audio choke lying around (or even a power transformer I wasn't using) I might use it for the plate. The resistor method works for some people and I'm not so sure why it didn't work for me. Maybe I need to play with it some more.

As for the throttle capacitor, I've seen some people do it that way. I'm more interested in keeping the operation simpler.

25834. Re-post of my Regen Project info/pictures

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-12 20:19:34 UTC
From: Phil
Topic: 25834 Message: 25834

On my Beacon mail list it was requested that I post (actually re-post) the information on the tube type regen receiver I designed/built this past summer. I thought it might be of interest to some folks here.

NOTE: This is basically a re-post of material I posted here in the past.

I DO still want to draw a schematic of the unit to share here, perhaps if I ever locate/download Tubepad or similar I'll be able to. . .
****
Good Mornin' (afternoon for you) Václav

Thank you for asking about my receiver. No manual, no schematic. When I designed/built it, I first sat down and figured out exactly what I wanted it to do, specifically be an above average regen designed for NDB DXing. A real tool, not a 1 or two tube 'novelty' set that would sit on the shelf and not be used. The ability to work other bands if desired was also on the list, which dictated the use of plug-in coils. More CW selectivity than a regen usually has, and the ability to drive either a speaker or modern low impedance headphones were also desired. BUT MOST IMPORTANT TO ME, I wanted the set to be based ENTIRELY on technology available to the experimenter in the 1930's, NO solid state active stages. I DID use silicon rectifiers in the PS simply because the transformer I used wouldn't support rectifier tube filaments etc.

Then I drew up a basic block diagram, knowing that the exact circuit would depend heavily on what electronic components I could obtain. So at this stage I didn't draw any schematics, but came up with a basic list of parts that I would need.

As project cost was going to be expensive IF I had to buy everything new, I then went on a scavenger hunt to see what I could scrounge up. I put a want list in our local ham radio newsletter, as well as some of the vintage radio and boatanchor mail lists I belong to, wanting to purchase old parts. Things like tube sockets, power transformer, audio output transformer, tuning capacitor and so forth.

This paid off nicely in a quite unexpected way. A man in Washington State offered me some adjustable 10H audio chokes, suitable for a 'passive' audio CW filter. Sent me three of them and they immediately became the components around which the entire receiver was designed. With capacitors they would form a parallel resonant circuit. They were tapped allowing the filter to have a low input impedance (plate) and high output impedance (grid of next stage). He also sent me an Emmco vernier tuning dial from the 1920's.

An almost local ham friend told me had a lot of stuff on my list, tubes, tube sockets, power and output transformers, old military style black

Bakelite knobs, potentiometers, etc, free for pick-up. Needless to say I drove the ~30 miles to get them.

Now things were starting to come together (this was a long summer project, NOT one to quickly complete). I took the stuff that I had gathered and laid them out on the workbench to get an idea of what sized chassis I would need. For rigidity/stability a good aluminum chassis was important. I ended up buying one that was 12x8 inches along with two aluminum bottom covers (one to use as a front panel). I thought it might be a bit large for the project, but in the end turned out to be the perfect size. At about $50 it was also the single most expensive item in the project, but I felt a necessity .

Once I had everything on hand I hand drew up the basic schematic of each stage, knowing that some of the circuits would be tweaked once I got the set working.

Next step was to set all the major components on the chassis to figure out the best layout. Important to keep the RF amp and detector stages as far as possible from the power supply (regen detectors are prone to hum pickup).

NOT a single hole was cut until I felt I had a good layout. I then drilled all the holes for the tube sockets, controls, transformers etc. NOTE: Not having any Greenlee chassis punches like I had as a kid in the '50s (they're VERY expensive now) I was told that a step drill like Harbor Freight sells is a VERY good, and possibly superior alternative. Reasonable in cost, effective, I now have five of them in different sizes, from a small 1/8" to a large 1-3/8". I even sent a couple to another member of this list so he could punch some tube socket holes.

I even drilled the holes to mount the Emmco tuning dial. NOTE: After I built the set I found that even with a lot of tweaking, lubrication etc, with it's relatively small tuning knob the dial was a bit too stiff to allow my arthritic fingers to tune it for long periods of time (remember, I said this radio was being built as a serious DXing tool). So I ordered a couple used National Vernier Reduction Drives from surplus WWII equipment and installed one. MUCH better and smoother, meant I had to enlarge the mounting hole and relocate the tuning capacitor slightly. . .

OK, I won't go into detail about how each stage was tweaked as I went along. But here's a description of each stage and what it does, following signal flow through the set.

1. 6AK5 tube, untuned Grounded Grid RF amplifier. Not there for gain, but to isolate the antenna from the following detector stage. A regen detector has high gain and easily overloads. The RF gain control is a Potentiometer in the cathode input circuit. There is also a 580KHz wavetrap at the cathode as 580 KMJ in Fresno (a 50kW station about 60 miles away) tended to bleed through on the high end of the NDB band.

2. 1/2 12AU7 dual triode. Armstrong Regen detector stage. The classic regen detector with tuned grid coil and a tickler coil in the plate circuit. Some other circuits, such as a Colpitts or Hartley were suggested to me on the Regen mail list, but I settled on the classic Armstrong circuit. Some folks have had problems with the circuit smoothly going into oscillation, but mine works VERY well (think it depends on the exact circuit parameters as to how smooth it is). This one is also EXTREMELY stable, after a short warmup of a few minutes, in oscillating mode it NEVER drifts more than a hundred Hz or so. NOT at all bad for a tube type free running oscillator!!! Of course this is at LF, it would probably be a different story at HF and above frequencies.

3. 1/2 12AU7 dual triode. Cathode follower loosely coupled to the plate of the Detector tube. It's output feeds a BNC connector on the back panel so that an external frequency counter can measure the actual receiver frequency when the detector is oscillating. NOT really out of the spirit of designing the set with '30s technology as it doesn't have any effect on how the set itself performs. It's there to facilitate dial calibration or to quickly tune the set to a desired frequency. I rarely use it in actual listening as it only works when the set is strongly oscillating, otherwise the counter just bounces around.

4. 1/2 12AT7 dual triode. First audio stage, audio filter driver. Not a lot to say about this one, it does what all audio amplifiers do, and it isolates the detector stage from the audio filter stage.

5. Passive audio stage. This is comprised of a 6 position switch, three parallel tuned circuits resonant at 400, 600 & 1020 Hz, and two RC Low-Pass-Filters (treble cut-off). First position bypasses all audio filtering, but I never listen in that "wide" position. Most of my listening is in the narrowest LPF position (treble-cut), switching to one of the bandpass filters when needed. The audio filtering is VERY effective in digging out weak beacons.

6. 1/2 12AT7 dual triode. 2nd audio amplifier stage brings the audio level back up after the losses introduced by the audio filters. The volume control is located between the audio filter and this stage. The set was intentionally designed with more AF gain than needed. At first the volume control was between the detector and first audio stages, but hum from the audio chokes in the filter was objectionable, especially in the headphones. Even though the chokes are in a shielded steel box, they still get 'some' hum from the nearby power transformer. Changing the gain distribution in the set by relocating the volume control completely removed it.

7. 6AQ5 audio output stage. Again, this section does just what it should, provide sufficient power to drive a speaker or modern headphones.

8. 0B2 Voltage regulator tube. Provides a stable 105 Volts to both the RF amplifier and detector stages. This is probably one of the contributors to the excellent stability of the receiver!

9. Rectifier stage. Uses 4 1N4007 diodes in a bridge configuration. My one concession to modern electronics in the set. The 'donated' transformer did NOT allow for a full wave tube rectifier, but I wanted full wave rectification as it is much easier to filter 120Hz than it is 60Hz. There is also a large DC filter choke in the B+ filtering circuit and VERY heavy filtering via the over-sized filter capacitors. That along with the 0B2 regulator means that the DC supplied to the radio is essentially "battery pure".

10. Filament circuit. As I mentioned, regen receivers are prone to hum and noise, often coupled from the filaments of the tubes. Part of the problem is that one side of the filament circuit often uses the chassis as a conductor, a bad design.

In this set I floated both sides of the 6.3 Volt filaments above ground, wiring with twisted wires. At the 12AU7 tube, both sides of the filament line is bypassed to ground with capacitors. In addition, there is a 100 Ohm pot wired across the filament lines, and the wiper is connected to the chassis ground. This is a "hum balance" control and is common in many older audio amplifier designs. The result is that between the well filtered B+ and the design of the filament circuit, there is NO audible hum in the receiver at all (outside of the aforementioned bit from the audio filter chokes, now almost completely gone).

FINAL NOTE: I've been asked a number of times if I'd draw up a schematic, and somebody suggested using "tubepad" software to do it. I've wanted to, need to locate the software, THEN FIND THE TIME TO DO IT

Pictures of the radio may be found here. . . You do NOT need a Photobucket membership to view/download the files.

Phil, great-repost and update. Send me a US passport and I will
vote for you as next President :-)

Every one of your thousand words is valued. Yet, if you could
hand-sketch the schematic, digi-photograph and post it, for one,
this still small voice would be extatic.

G'day Prof Coro (and others),
Thank you for your invitation to try the 6EJ7 (& co) pentode as a detector.
I'll say "no" until I have test equipment that will allow me to measure the effect of small changes to my sets.

Let me explain: Before now I mentioned experiments with coil and capacitor - pages published by a Dutch experimenter. His experiments focus on measuring and improving the "Q" of a tuned circuit. Using only simple equipment (signal generator, C.R.O. and so on) his pages describe the process of imrpoving the "Q" of a coil & capacitor to the point where he achieved a "Q" in the order of 1000. That was from a starting "Q" of about 150.

The point here is that each experiment only gained a few "Q" points ("Q" points are imaginary numbers, of course, but I think you understand my words well enough). I think it would be impossible to measure the improvement without his simple test gear - a signal generator, C.R.O. and detector probe.

I believe the same is true for the simple regen sets we build. We can build, test and observer - but without reliable measurements we can't accurately say, "This is an improvement". There is the question of selectivity - discussed here from time to time. Some say selectivity can't be measured using a regen set, beacause "Q" varies with the setting of the regen control. True but it IS possible to measure in at a particular setting. I say, "I'm going to do it." When I make these observations I DO hope I can develop the same careful style of observation used by our Dutch friend. Reading about his experiment is a delight - such careful planning, such simple improvements - all leading to a completely unexpected result! Who would imagine it was possible to obtain a tank circuit with such a high "Q".

For that moment that's what I'm going to do - focus on getting simple gear to make this sort of measurement. Then - and only then - I think it's worthwhile comparing tube types.

73 to you from Australia!

Les

25837. Re: EF183 tube Regen Circuits and further information about tips towards an optimized regenerative

Yahoo group: regenrx (2016 — 2017)

Dear amigo Frank W4NPN
Nice to hear from you and learn about your interest to build
vacuum tubes regenerative receivers.
Amigo from Italy , Cris, circuit diagram is a REGENERODYNE...
a receiver that has a classic HF mixer and local crystal oscillator
feeding a regenerative detector.
Then this is followed by enough audio gain as you want to
provide enough output for a loudspeaker.
In the case of the ECH83 and ECH81, you feed the triode
tube from the mixer, and do the actual tuning by means of
the regenerative detector that has a plate voltage control
to adjust the operating point .
This circuit works very well, but you are tied to having quartz
crystals for the frequencies that you want to pick up.
Let me explain... with a 5 megaHertz crystal , and having the
tuning range of the triode regenerative detector covering from
2 to 2.5 or maybe 2 to 3.0 megaHertz, then you can listen to
7.0 to 7.5 megaHertz or 7 to 8.0 megaHertz. Then there is also
the option of REVERSE TUNING:... by subtracting 2 megaHertz
to the 5 megaHertz , you can tune 3.0 to 3.5 or 3.0 to 4.0 megaHertz
In this case the receiver tunes ¨backwards¨ You will need to
make the input rf circuits resonant to the frequency range you
want to pick up.
If you ask me about what is the best vacuum tube regenerative
detector, I can pass along my experience of many experiments...
Using a 6AK5 / 5654 /6ZHE1P in the Hartley configuration, with
the carefully set cathode tap on the tuning coil and using
a high quality potentiometer to control de screen grid voltage
with about 20 to 50 volts on the plate (again experimenting is
worth the time and it is a lot of fun) you will find that the
screen grid voltage variation between about 3 to 5 volts and
up to about 20 to 25 volts will produce a really very smooth
transition from straight amplification (grid leak detector)
to a regenerative detector that can be set at the very sweet
spot that provides razor sharp selectivity and still will not
be oscillating ....
Also the power supply will require a lot of attention amigo Frank
something often neglected by builders that then say that
the regenerative receivers do not work very well.....
Build them like a battleship, use a lot of shielding between stages,
remember to use regulated DC on the filaments of the detector
tube and if possible on the audio stages also... something that
nowadays is very easy to do with the typical IC integrated voltage
regulators.... The voltage for the plate and the screen of the

regenerative detector MUST also be well regulated.... from a
gas discharge tube, like a OA2 etc. or by means of Zener diodes...
Again , my advice is to build your power supply separate from the
RF and Audio modules.... and it will provide you with a nice
unit ready to be connected to whatever experiments you want to
put in practice... The B plus for the audio module not to exceed
150 volts... better yet try around 100 to 120 volts DC non regulated...
The ¨high voltage¨ uses 4 silicon diodes of type 1N4007 with
,01 disc ceramic capacitors in parallel, then two high capacity
electrolitics and a 7 to 15 Henry choke.... I use recycled
capacitors from computer power supplies, typically around 220
microfarads or more at no less than 250 volts or higher... Use them
ONLY after measuring their ESR, equivalent series resistance...
Hope this helps you amigo...
Winding the coils is a lot of fun !!!
AND... a good quality air spaced variable capacitor with a
very good dial mechanism is essential to achieve the best
possible results.... I have ARC-5 receivers and transmitters
capacitors, but better yet , try to hunt for a BC221 heterodyne
frequency meter or the similar LM or the Russian CHA4-1
clone...

25838. A few comments about your message to the list explaining the use of an Armstrong regenerative

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-13 17:34:22 UTC
From: Prof. Arnaldo Coro Antich
Topic: 25832 Message: 25838

Dear amigo Ed---
Please notice that you have a fixed 200 pF capacitor to return
to ground the tickler coil !!!
My advice is to try to use instead an air spaced variable capacitor
of around 300 picofarads if your radio is for the AM broadcast band.
Then you will have not one but TWO regeneration controls... this
new variable capacitor and the already existing 100 kiloohms
screen grid voltage control.
I also suggest replacing the 100 kiloohms fixed plate resistor with
a high inductance choke.... The value of that part may be as
high as 300 Henry , or as low as 10 Henry.... and in both cases
in my opinion it is a better option than a fixed carbon load resistor
for the plate circuit.
That's about the Armstrong regenerative circuit...
BUT, I prefer to use the same pentode regenerative detector
as a Hartl

Hello all,

I'm contemplating another regenerative receiver design to make soon.
Here's a link to a schematic that will be similar to my detector
stage. I intend to control the oscillation with voltage to the screen.

http://www.angelfire.com/electronic/funwithtubes/Regen_det.html

I intend to use an Armstrong-type feedback mechanism as shown. One
thing I intend to do differently is to have plug-in coils with a fixed
capacitance across each one. The fixed capacitance has been calculated
in order to reduce the tuning range. Using a small variable
capacitance of 8-40 pF, I'll be able to realize ranges of 500-750 KHz
instead of several MHz per coil.

Is there a reliable way to determine the number of turns on the
tickler coil? I've built many regenerative detectors and have had
problems making some of them oscillate. It's possible that I didn't
have a strong enough tickler winding, therefore not enough fed back
signal to make the thing oscillate.

Also, I have had problems with this particular design. As you increase
the pot on the screen, the voltage increases and the tube conducts
more. There's a point at which the tube conducts the most and I hear
the strongest signal output. After that, any further advancement on
the control lessens the signal. It's because the 100K resistor in the
plate circuit causes the plate voltage to drop, reducing its
effectiveness while increasing screen current. I'm not sure if there's

anything that can be done about it, though.

I would appreciate shared experience with these problems. My intended tubes are 6EH7 and 12AU7 or something similar. I could also use 6SN7 and some octal pentode, too. I'm pretty sure I want to use 9 pin tubes, though.

Ed AE7TE

I've built the receiver section today. It works well. Very sensitive and stable. I added the attenuator and using BC547s from my stock. Sorry but I feel my version is not a "Single Signal". Both CW sideband has receiverd well. hi...Anyway I will continue to test this receiver.

Thanks Rob "KB3BYT" for sharing your resonator!

I put my schematic into file folder.

73,
ja9mat Hidehiko.

I think you could probably make this into a kind of single-signal receiver by using the ceramic-resonator as a Q-multiplier, and injecting a separate BFO signal (which might be generated by another ceramic resonator VXO). Adjust the Q-multiplier just below oscillation, and tune it to peak your signal of interest, making sure it stays below oscillation. Then, turn on the BFO (injected into the Q-multiplier) and adjust it until you hear the beat note. If you do this, you should be able to notice that signals on one side of zero beat are stronger than on the other side of zero-beat, i.e. some degree of opposite-sideband suppression. It's easiest to notice if you manually sweep a signal generator across the regen's passband. You can also tune the below-threshold Q-multipler to peak individual CW signals. It's also fun to connect the AF output of your regen to an AF spectrum analyzer (like one on your PC) and observe the location and strength of your Q-multiplier-generated peak, as you tune the below-threshold Q-multiplier across the band.

I tested this a few years ago with a normal LC-resonator regen and an LC-resonator BFO, and got around 20 dB of opposite sideband rejection if I recall correctly.

Dave Newkirk has pointed out before that this kind of below-threshold regenerative selectivity collapses in the face of strong signals, which limits its usefulness, because strong signals are exactly the case where selectivity is most needed. That said, it's possible your ceramic resonator regen may be more resistant to overload than an LC regen.

Anyway, it's worth a try (below-threshold regen + offset BFO) if you enjoy playing with regenerative selectivity.

Best regards,

Hello qrp.gaijin

I had a similar idea, this is my actual version:
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/80m_Resonator_Regen.gif
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/80m_Resonator_Regen.gif

I can confirm the 20 dB sideband attenuation. But i am not really satisfied, the circuit reacts too sensitive on the ratio between signalstrength and bfo amplitude. When the bfo is too strong, it overruns the regen circuit and selectivity is getting lost. What i want to try next, is a DG-MOSFet as a product detector, while keeping the bfo signal away from the regen.

Another observation: When tuning the regeneration potentiometer, a BF199 shows only 1/10th of the drift compared to a 2N3904. Until now i could not syncronize the two resonators, therefore i use two separate variable capacitors.

Best regards,
Bernd

I just uploaded what U think is the final update of my Mk.7. I got rid of the 12FQ8 in favor of a more reliable cascode regen circuit. It performs pretty good, but is disappointing on SS. Now I think I'll do some mods on my Mk.8.

Leonard

Just wrapping some brain cells around circuit design here......

Is there any reason varactors were used instead of variable capacitors
in this radio ?

There was a couple of reasons that varactors were used in my Mk;7 (and others) I normally use varactors for band spread because I can tune multiple circuits with one panel control, and the control can be mounted anywhere on the panel. In this case, the 2 section varicap I had was only 60pF so I used it for band spread and used MVAM109's for band set. Lastly, I had a bunch of MVAM109's that needed a job. BTW, I noticed some errors and ommissions after I posted the schematic, so I'll be correcting them shortly.

Leonard

Cool.
Thanks for the explanations.
I have a bunch of 1SV149 varicaps here but did not put to use yet.
I was working on understanding basic RF regen tube circuits before
moving into newfangled sand state devices.

I put the revised schematic into file folder. The TX is about 400mW into the dummy load and has a QRH around 100Hz while keying. The characteristic tone I like. And I misunderstood about the "single signal" thanks for suggestions.

ja9mat.

25855. Re: a first regenerative radio power supply and the rest of the circuits advice reply from Arnie

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-15 17:41:21 UTC
From: Prof. Arnaldo Coro Antich
Topic: 25855 Message: 25855

Hola amigo Raj
Then when you finish your regenerative receiver in its very first
version, you can calibrate the dial to tune to 6000 kiloHertz, the
frequency that we use every evening to broadcast in English
to the USA.
The separate chassis is only for the power supply, because once built
and fitted with the proper connectors or screws type terminals
you can use it for many projects...
The main radio itself goes into one single chassis, but I have built
some on a piece of good quality printed circuit board using the
insulated islands cut from PC board and glued to the main board
that serves as a perfect ground plane connecting area.
My advice , after you have fully tested the power supply is to
follow by building the audio module, and then test it ... If you
do not have an audio oscillator, then just touch with your finger
the top of the audio level control potentiometer with the loudspeaker
connected of course... BIG HUM will be heard !!!
Ideally I test the audio module with my nice variable frequency
audio oscillator ... starting with a 1000 Hertz tone, at a nice low
level, and then sweeping from 100 Hertz up to 5000 Hertz...
I also try to detect any background hum... that will be almost
nonexisting if the power supply is working OK

Next step is to build the regenerative detector stage... with a
simple LC tuned circuit ... You will want to make a coil for
the range from about 5 or 6 megaHertz up to about 10 megaHertz...
Using the commonly available air spaced variable capacitors
a coil with about 15 turns close wound , with the cathode tap
around turn 3 or 4 , will work quite well with a 250 to 350 Picofarads
maximum variable capacitor.... At night , even with just a short
length of wire connected to the two turns antenna link, many signals
will be heard... and the six megaHertz international broadcast band
can be easily found... If you have an RF signal generator, then
calibration of the dial is very easy...
You will be surprised how smoothly the regenerative detector approaches
the critical oscillation point... When it is very near
that point if shows the maximum sensitivity...

Hello,

this video demonstrates the amount of attenuation, when using a bfo. The circuit is just that one above. I'm tuning a signal generater a few khz up and down. Turn your loudness up, otherwise it is hard, to hear the other side.

From: Hubert Miller
Topic: 25860 Message: 25860

"When Not to Bloop

To keep amateur radio from getting a black eye, we suggest that you not try to copy the signals of planes attempting transoceanic flights with a radiating blooper unless you live at least 100 miles or more from any population center or department of commerce or airways station. An r.f. stage ahead of the 'blooper' regenerative detector will cut down the radiation from the receiver, but will not entirely eliminate it, and the receiver may still cause interference to receivers a few blocks away when receiving weak signals.
the c.w. signals of a plane on a recent trans-Atlantic flight were obliterated during part of the flight by several radiating receivers. It was
not possible to copy the signals when they dropped below R6 because of the many 'birdies' on the frequency.
An Associated Press dispatch stated that 'amateur radio men were trying to pick up Merrill's plane, making it increasingly difficult for the air line to receive the plane's signals.
That sort of thing does amateur radio no good."

from RADIO, Jun 1937, 23.
Not posted here to stir up controversy again, but to maybe show concerns at the time, and what "could" happen with regen receivers,
long antennas, and good propagation - - maybe!

Hi Bernd,

Very nice demonstration of single-signal reception by achieving single-signal regenerative selectivity directly at the radio frequency.

Judging by ear, the opposite-sideband suppression you achieved with your ceramic resonator circuit (at 3.5 MHz?) sounds better than what I remember achieving with an LC circuit at 7 MHz.

As you hinted at in an earlier post, one problem is tracking the Q-multiplier tuning and the BFO tuning. Without such tracking, I wonder how usable such a scheme is in actual practice -- you have to adjust at least 3 controls to tune in any one signal (BFO tuning, Q-multiplier tuning, and Q-multiplier regeneration level).

Best regards,

There was a concern during WW2 about radiation from the LO in superhets as well as regenerative receivers. Stories could be apocryphal.

I do remember my father mentioning the issue of regenerative receiver radiation in the early days of radio -- late 20s, early 30s -- causing interference on the MW bands.

I would think a buffer amplifier on the input would tend to help that issue, as well as stabilize the detector against antenna "pulling" issues.

25873. Plugin Coils

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-22 21:39:06 UTC
From: Leonard Meek
Topic: 25873 Message: 25873
Attachments: 1 described; binary payloads are missing from this source WARC

I noticed some time ago that my plugin coils were not matched. It doesn't seem to matter at the lower freqs but becomes quite noticeable higher up. So I threw together a little jig for matching the coils, although I have yet to test them. I'll be doing that tonight after the airways come alive. Meanwhile, here's what I came up with. It's only intended for the grid coil, but can be expanded for others.

Leonard

That was arguably the dumbest statement I've made in this forum, for _it disallows the operation of the tube as an amplifier_. The interposition of the (ac-grounded) screen between grid and plate greatly reduces _capacitive_ coupling between grid and plate--in RF tubes, that's why we add Grid 2 and that's why we call it a screen--but _of course_ its presence does not preclude _electron coupling_ between grid and plate. And so putting the Armstrong tickler in the plate is merely making use of the tube as an RF amplifier. Arguably, because there's amplification from grid to plate, the use of a screen-grid tube in an Armstrong-feedback regenerative detector should allow (a) the use of lighter feedback coupling than one would need for a triode; (b) a lower-inductance tickler coil; or (c) both. Also arguably--and here's a fun controversy for oscillator historians--an Armstrong-feedback oscillator or detector with its tickler in its plate circuit is therefore no less an _electron-coupled_ oscillator than later circuits (such as Dow's contribution: a tetrode Hartley with screen ac-grounded and output obtained at the plate) for which "electron coupling" was the claim to revolutionariness and fame.

Regenerative detectors that use an Armstrong-feedback-equipped screen-grid RF tube in this way include Grammer's ac-heated regen from December 1930 _QST_, and the detector in National's SW-3 receiver (detailed in an article by James Millen in September 1931 _QST_).

Right, so if you can accelerate to 60 mph faster in a Mustang than some herking Peterbilt truck, the Mustang is "better"--no further discussion needed. Or you could acquire a bit of knowledge to grok that the Peterbilt is engineered for power and not for speed.

Try "different" performance, not better. No modern well-engineered commercial HF transceiver will be practically less sensitive than a regen when properly applied. Because modern transceivers and receivers are designed to use a low-impedance antenna--"50 ohms"--what can make a regen _seem_ more sensitive is a scenario like this: Lightly couple a 10-foot wire to the "top" of the tuned circuit in an RFamplifierless regen, hear a given weak signal at, say, 40 meters, and then switch out the regen and connect the same antenna to a modern, commercial HF radio. Now the modern radio seems deaf compared to the regen. Of _course_ it does: A very short wire presents a high impedance at 40 meters, and such an antenna won't produce much input-signal wiggle in a radio optimized for 50 ohms. The regen performs "better" because you are _misapplying_ the better-engineered radio.

I get that you generally don't use your transmitting antenna for receiving and don't see the engineering basis for discussing the issues involved. Such discussions are, it seems, all about math and spreadsheets and squiggly graphs. I'm glad you're having radio fun.

I am myself an aficionado of R. B. Bourne's "I Can't Be Bothered" (http://dpnwritings.nfshost.com/ej/bourne_193207.htm http://dpnwritings.nfshost.com/ej/bourne_193207.htm) However:

Readers of this forum new, well-seasoned and in-between: There's endless self-instructional gold in learning not to mistake the special case for the general and in perpetually recalibrating what you know and understand so you stay aware, and expand your knowledge, of the difference. To some of us, that process is part of the fun.

Best regards,

Dave

The antenna can be connected onto Pin 1 of L1 by a small cap of a few pFs. Or L1 can be used as a ferrite loopstick antenna.

Hello,

I'm sorry I've deleted my version of the schematic diagram because I'm still experimenting every weekend.

Now I put the latest my version into the file folder.

The transmit final is replaced with 2SC2053 for stability and some values has changed for my situation. BD139 has sometimes self oscillation. The transmit signal has a little shaking at keying. But I like it! hi.

The output power is about 500mW to 600mW into the DUMMY LOAD.

ja9mat Hidehiko.

25885. Versatile Regen with an emitter coupled oscillator.

Yahoo group: regenrx (2016 — 2017)

From: dawmast@...
Topic: 25885 Message: 25885

Here I have a schematic of the Versatile Regen.It has a very useful and a reliable Q-Multiplier with a differential pair around T1 and T2 (emitter coupled oscillator). The 1N4148 diode (D2) provides a reverse bias for the basis-collector junctions of both T1 and T2. This measure reduces the basis-collector capacitances of these junctions, by which the detuning of the tank circuit by T1 and T2 is reduced. Due to the fixed voltage over D2, the voltages over the basis-collector junctions are fixed too. The voltage swing over the tank circuit can be higher before it is current limited when the base-collector junction diodes start conducting. A Q-Multiplier with a differential pair is very easy to build, has a smooth regeneration control, has a wide tuning range over which it can oscillate and it has no problems with squegging and severe loading of the tank circuit due to the small coupling capacitor C1. T1 is an emitter follower which does not load the tank circuit very much.The coupling coil between terminal 3 and 4 of L1 to the detector stage with T3 must not be too big, otherwise regeneration backlash will occur due to the too strong coupling of T3 to the tank circuit. When you use a FET as a Drain Bend Detector which is connected onto the top of the tank circuit, you can use a single coil for L1 with no taps or link windings. I think that a differential pair as a Q-Multiplier is the best type you can use with BJTs, in contrast to the more common Armstrong, Hartley, or Colpitts type Q-Multipliers which are more difficult to optimize.

25887. Mk.8 Regen

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-27 23:43:04 UTC
From: Leonard Meek
Topic: 25887 Message: 25887

I just posted the final update on my Mk.8 regen. I can't think of anything else I can do to it, except maybe add AGC. The component values are pretty much optimum but not absolute. I matched the coils as best I could, but the RF comp is still used to compensate for stray capacitance in the circuit wiring. It tunes from about 0.5 MHz to about 25MHz and has very little drift after a few minutes warmup. SSB is fair. It gets most whatever my SP600 gets, though not any better. It's time to move on.

Leonard

Hi Leonard, I studied your circuit with great interest. You observe that you resolve S.S.B. well. You don't say superbly - you say "fair". I understand this to mean 'good enough' but you have seen better.

I see you regulate the supply to the detector using a 1N1372 zener. My book shows this as a 75V regulator. 10 watts, I think. The page is blurred a little. Minimalists don't regulate the B+ supply, but that seems to give superior performance.

You use a pentode as the detector; using the Armstrong "tickler" circuit, rather than the tapped-coil Hartley. This is interesting. In these postings David Newkirk suggested that the Hartley circuit uses the screen "in-lieu" of the anode and observed that the screen is grounded. His argument was (if I understand correctly) that the RF that "leaks thru" to the plate was by chance, not design. Yes, this is rather unfortunate language - chance & design - but his point was that the cathode is above earth, not the anode, and that any RF on the screen or anode is "leak-thru", and the cap on G2 proves that point.

So - my first question - in your other sets, do you have the Hartley detector, and would you comment on Hartley vs Armstrong tickler (with a pentode).

Q2 is about the type of tube you use for the detector. You show 6K7 - a sharp cut-off pentode. So you have ever tried a 6K7 - the so-called "remote cut off" (or variable mu) type? If "yes" what difference do you report?

I notice you regulate the heater supply. Bill Cromwell and Arnie Coro do that too. That practice gives greater stability. This take away from the minimalist approach, but seems necessary to get good performance, yes?

Finally, you have 3 stages of A.F. gain before the speaker. Do you need that much gain?

Altogether a nice set, I think; certainly an interesting circuit to study closely - as I did.

Les, thanks for the scrutiny. I copied this circuit from the RCA tube manual, with a few modifications. I used the Armstrong circuit because the coils I was using were 4 prong coils and didn't allow a tapped secondary. Also, that's what the RCA circuit used. I tried the 6K7 as the detector but I found the 6J7 was more sensative. I have used the screen feedback on some circuits with good results and would have used it here, but this set is working so well now that I just decided to let well enough alone. The regulated heater supply was a simple way to get the 6V for the detector & first AF, and resulted in some stability as well. As for the 3 AF stages, I had the space so why not? It's easier to reduce a strong signal than to boost a weak one. I'm still exploring the posibilities of AGC. I tried audio derived AGC on one of the sets with disappointing results. I feel IF derived AGC is the way to go.

Leonard

From: les.au49@...
Topic: 25887 Message: 25890

Hello Leonard! Wow! I always wanted to know about the difference between using a "sharp" vs "remote" cut-off tube (as detector). I don't think I'll get better information than your observation because (1) you used the different tubes in the same circuit and (2) the tubes - 6J7 & 6K7 - provide "side by side" comparison from tubes of the same era (when engineers thought "tubes"). It's possible, of course that your tube was "sus" in some way - but unlikely.

Commenting on the the other points - regulated B+ supply to the detector and heaters - yes, I'm sold on those two points. I can say that Bill Cromwell (hello Bill!) is the great influence on this point; he mentioned it first (or foist, if you come from the Bronx). If you're a minimalist, of course, don't do it, but for those who look for best performance the benefit is good and the cost small.

On the question of A.F. gain, can you say if you need that third tube?

Finally, on the point of AGC - I would tend to think "solid state" - and worse than that to IC's. Yes! Integrated circuits! They are lovely! I would build a circuit rather like a control circuit where I set a "target" voltage, and amplified the difference between target and signal and amplified that difference to use as gain-control. That - suggests a dual pot - one to set "the target" and the other to control final volume. This idea could be easily implemented using an op-amp. In the "standard" AGC system an implied "target" exists - somewhere, but it's not stated explicitly. Non-tube "types" will dislike my idea.

I think the problem with audio-derived AGC is the conflicting requirement that it work at different levels of volume, while at the same time it is derived FROM volume. The concept confuses what is controlled and what is controlling. Audio AGC is fine - until you want to vary the output.

Thanks for publishing your circuit.
Great work!

25892. Ant coupling to a Hartley regen

Yahoo group: regenrx (2016 — 2017)
Date: 2016-02-29 17:07:17 UTC
From: Hubert Miller
Topic: 25892 Message: 25892

With the Hartley tapped-coil regen detector, there have been some project schematics showing the antenna connected to the coil

tap instead of to the top of the tuned circuit or a separate antenna winding. Has anyone tried this? I am wondering how this

compares with a separate antenna winding. If the antenna coupling with the antenna connected to the 'cathode tap' is still too

tight, and if it works better with a separate, lower tap on the coil provided for the antenna point. Of course i mean a simple

0-V circuit, which means one with no RF stage.

thanks-

Hue Miller

There is no "one size fits all answer" because how much coupling is appropriate between antenna and detector depends on the antenna in use and the perturbability of the detector. (A high-C detector can generally stand more signal input--is harder to perturb--than a lower-C one.)

And another thing to keep in mind is that we in no way are talking about any sort of impedance matching here. To the contrary, increased power transfer from antenna to detector will also increase power transfer from the detector to the antenna, ultimately lowering regeneration and even disallowing oscillation. This can lead to "dead spots" in tuning ranges.

So all we're really doing in tapping the antenna up and down on the detector coil is adjusting how much signal gets to the detector from a greatly impedance-mismatched antenna. We're actually putting that mismatch--and the attendant _mismatch loss_--to work as means of controlling the detector's signal diet.

That said, tapping the antenna up and down on the tuned circuit directly and tapping the antenna up and down by means of a coupling winding of more or fewer turns provide exactly the same effect in practice. A Hartley detector just happens to give us two ready-made tap points: The top ("hot") end of the coil and the cathode-tap point on the coil. You try whichever seems to work better and call it done.

In practice, especially with longer antennas, the impedance of which can vary from high to low depending on wire length and the frequency of interest, one tap point may well allow the detector to work acceptably well while the other tap point doesn't. So you use the one that subjectively "works better" in any way that seems appropriate--signal strength, smoothness of regeneration, detector stability, detector resistance to overload, whatever. That neither may offer no clear advantage at a given frequency with a given antenna doesn't mean somethings wrong or needs redesigning; it also doesn't mean that the ability to choose between the two tap points won't matter at _some_ frequency with that antenna. Try, try, try.

Best regards,

Dave

> and then surge back up again when the sound started up again.

You're not alone in this experience; it commonly happens with audio-derived AGC even in otherwise soundly designed superhets.

The first cause of the problem is that audio-derived AGC requires the rectification of audio, the number of cycles per second of which is much fewer than the number of cycles per second when the signal being rectified is RF. Charging the capacitor(s) in the AGC circuit therefore takes so relatively long that enough milliseconds pass for the AGC to ramp up to allow a few milliseconds of AGC-_un_controlled audio to get through as a loud pop.

Secondarily, unless your AGCed AF stage[s] operate in push-pull and the control voltage is applied to those push-pull devices in parallel such that any AFish transients on the AGC line cancel in the output of those push-pull amps, the control-voltage steps that are applied to the AGCed-stage grids will itself be audible as noise or audio intermodulation in the output of the AGCed stages. (In the back of an RCA _Receiving Tube Manual_ or three from the 1930s and/or 1940s, the example circuits at the back of the book include an audio compressor circuit that's based on two push-pull 6L7 mixer tubes with their "mixing signal" grids AGCed in parallel to avoid exactly this effect.)

It might be possible to preserve the fast attack of RF-derived AGC with the cleanliness of regenerative- or direct-conversion-receiver audio by converting the detector AF output to RF _just for the purpose of rectifying it to generate AGC_, and then applying the AGC voltage so derived to AF rather than RF or IF stages. This would be an application of _sidechain_ AGC--a system in which a separate IF or RF amplifier chain is used solely to generate AGC for application to an entirely separate amplifier chain. Push-pull AGCed AF stages would still be necessary to keep transients on the AGC line from getting those stages' outputs as pops or IMD noises.

My thoughts exactly, sort of. I've decided to forgo AGC on my regens and maybe try it on the regenodynes. At least there would be a carrier to work with.

On a different note, I was listening to Radio Romania tonight on about 7.34 MHz at 0400 UTC for a half hour. The signal was loud and clear here in Hawaii and there was no sign of fading. The sound was kind of tinny with a slight echo. Are they using a new kind ot transmission? I notice all the adjacent stations fade in & out normally. Just curious.

Attachments: 2 described; binary payloads are missing from this source WARC

Actually, we are sort of talking about an impedance match, if only within roughly defined bounds, nowhere near as stringent as for an apparatus

intended to deliver power to the antenna. As Dave says, too good a match with too close coupling and a smooth approaching regeneration becomes

touchy or regeneration is even lost. But transformer coupling to the tuned circuit via a primary or autotransformer tap does present a better transfer

of signal voltage when using a typical low-Z hamband antenna accessed via coax. And a short antenna of say, just a few feet, of course goes to a high

impedance point. (A resonant antenna will add one more ‘pole’ of selectivity, but the Q is quite low, probably only useful for discriminating against

out of band signals and noise.)
It’s always kind of amazed me how well the good old trimmer capacitor to the top of the tuned circuit works, even when the natural resonance of the

antenna is low at the tuned frequency. I suppose you could say the trimmer reactance cancels part of the antenna’s resonant inductance – as well as

limiting the voltage transfer. Connecting the antenna this way does allow for a wider range of antennas than circuits with only a low impedance input.

But the “real life working job regenerative receivers”, i think, all used transformer input, and they all seem to use the Armtrong – Reinartz tickler coil

circuit. At least those i seem to be recalling now. I think their input Z was characterized around 500 ohms, sort of a compromise high – low.

There is no "one size fits all answer" because how much coupling is appropriate between antenna and detector depends on the antenna in use and the perturbability of the detector. (A high-C detector can generally stand more signal input--is harder to perturb--than a lower-C one.)

And another thing to keep in mind is that we in no way are talking about any sort of impedance matching here. To the contrary, increased power transfer from antenna to detector will also increase power transfer from the detector to the antenna, ultimately lowering regeneration and even disallowing oscillation. This can lead to "dead spots" in tuning ranges.

So all we're really doing in tapping the antenna up and down on the detector coil is adjusting how much signal gets to the detector from a greatly impedance-mismatched antenna. We're actually putting that mismatch--and the attendant _mismatch loss_--to work as means of controlling the detector's signal diet.

That said, tapping the antenna up and down on the tuned circuit directly and tapping the antenna up and down by means of a coupling winding of more or fewer turns provide exactly the same effect in practice. A Hartley detector just happens to give us two ready-made tap points: The top ("hot") end of the coil and the cathode-tap point on the coil. You try whichever seems to work better and call it done.

In practice, especially with longer antennas, the impedance of which can vary from high to low depending on wire length and the frequency of interest, one tap point may well allow the detector to work acceptably well while the other tap point doesn't. So you use the one that subjectively "works better" in any way that seems appropriate--signal strength, smoothness of regeneration, detector stability, detector resistance to overload, whatever. That neither may offer no clear advantage at a given frequency with a given antenna doesn't mean somethings wrong or needs redesigning; it also doesn't mean that the ability to choose between the two tap points won't matter at _some_ frequency with that antenna. Try, try, try.

Best regards,

Dave

One of the most important aspects regarding how to make the
incoming radio signal feed the detector circuit * in this case
a regenerative detector with no RF amplifier * is to be able
to provide a very precise degree of coupling to the detector
coil... This is accomplished in one of my favorite regeneratives
with a mechanical system , controlled from the front panel, that
moves a single or two turns air wound coil that slides, more or less
separated , from the grid tuned circuit coil...
This is in essence an inductive plus a little capacitance coupling
system, that has proven to be extremely effective in delivering to
the detector the proper level required for good signals pickup...
When using one RF stage ahead of the detector... in the untuned
grounded grid configuration...one can install a good quality
potentiometer to the cathode of the triode, and feed the signal
via a capacitor to this resistive attenuator control !!!
Likewise , when using a tuned RF amplifier, you can use a good
quality carbon potentiometer between the antenna and the
coupling link coil ... values between 1k and 10 k seem to work
well....

Hi Arnie,
Is there a picture of that mechanical system anywhere on the web?

and
did you get the 7.16 Mhz resonators I mailed to you?

HOLA AMIGO!!!
Not that I remember... I saw that very clever variable coupling link
on an article in an old ELECTRIC RADIO US magazine, devoted
to vacuum tube equipment... The photos show how it is built for
a regenerative receiver that uses a 6J5 triode as the detector...
I do not have a scanner.. but maybe it would be possible to take
a photo of the article, if I can locate the ELECTRIC RADIO issue
in my not too well organized library !!!!
So far no message from the post office to go and pick up
something...
It seems likely that soon , after more than 50 years of INCOMMUNICADO
postal services, regular mail will be started between our two
nations...according to a recent joint press release by the Correos de
Cuba and the US Postal Service...
Up to now, all correspondence has to go routed through a third
country !!! And much of it is lost or pilfered in the case of parcels !!!

WOW !
I found it.... together , mixed into the stack of SPRAT Magazine, the
G QRP Club publication.
ELECTRIC RADIO
NUMBER 134
JUNE 2000
PAGES 20 TO 27
A WONDERFULLY WELL WRITTEN TECHNICAL ARTICLE ABOUT
REGENERATIVE RECEIVERS....THE 6J5 REGENERATIVE DETECTOR
CIRCUIT THAT THE AUTHOR USES WORKS VERY WELL, WITH
A NICE SMOOTH REGENERATION CONTROL ...
I tried it with a 6C4 and also with half of a 12AU7 * same as 6C4 *
then an attempt to use the 12AT7 / ECC81 did not worked so well
possible to it having a much higher MU * amplification factor "
May I suggest also that all of you download the ZL2JJ Regenerative
Receiver because it a pacesetter of all times, including the
magnificent mechanical construction... The one I built years ago
had newer , but similar vacuum tubes, but my very limited
mechanical abilities, and lack of a machine shop * the two combined
against me * made me dis-assemble my ZL2JJ for recycling some
of the hard to find parts....

Arnie, my Mk.8 regen is similar to the ZL2JJ and it works very well. But I see several things from his schematic that I can use to improve my set. I'm currently working on my Mk.14 and I still wonder how I can receive Radio Romania here in Hawaii so clearly with no fading. There seems to be a slight echo, so I wonder if the signal is coming from two sources. Just curious.

Hola amigos !
During periods of very low solar activity, around the spring and autumn
equinox we always see some very interesting propagation enhancements
that last for a few weeks before, during and after the actual equinox
days * minus and plus around a week *
Sometimes I receive similar reports about how Radio Havana Cuba
is heard in Australia and New Zealand very well twice every year
with especially good signals on the 5000, 6000 and around 9.5 megaHertz
When the Earth receives equal solar radiation the propagation
enhancements are more noticeable !!! And sometimes, when using
almost non directional transmitting antennas, signals can travel
from East to West , and also along the LONG PATH too. The LONG PATH
introduces a delay so that when both signals reach Hawaii, Australia
and New Zealand you hear a sort of ECHO, or maybe a tinny sounding
audio !!!
Propagation of signals from 3 to 30 megaHertz via an ionized medium
is still something that requires more research !!!
I have made radio amateur bands contacts using 100 milliWatts to
a zero dB gain antenna ... and regular CW !!! Moving to 10 milliWatts
carefully checked with proper measurements still delivered
a useful signal at the other end of the 2000 kilometers skywave path !!!

enhancements are more noticeable !!! And sometimes, when using
almost non directional transmitting antennas, signals can travel
from East to West , and also along the LONG PATH too. The LONG PATH
introduces a delay so that when both signals reach Hawaii, Australia
and New Zealand you hear a sort of ECHO, or maybe a tinny sounding
audio !!!
Propagation of signals from 3 to 30 megaHertz via an ionized medium
is still something that requires more research !!!
I have made radio amateur bands contacts using 100 milliWatts to
a zero dB gain antenna ... and regular CW !!! Moving to 10 milliWatts
carefully checked with proper measurements still delivered
a useful signal at the other end of the 2000 kilometers skywave path !!!

Arnie, my Mk.8 regen is similar to the ZL2JJ and it works very well. But I see several things from his schematic that I can use to improve my set. I'm currently working on my

Mk.14 and I still wonder how I can receive Radio Romania here in Hawaii so clearly with no fading. There seems to be a slight echo, so I wonder if the signal is coming from two sources. Just curious.

THANK YOU for the link

I don't know why but I did not get this web page when I GOOGLEd "ZL2JJ Receiver"
This interweb is a funky thing sometimes.

re: What exactly were you looking for?

PICTURES

Without including all the emails... just sort of nutshell recap....
I may not get it all correct but I think it went like this:
Arnie posted a description of a mechanical linkage that worked for
receivers which gelled into ZL2JJ projects.... pointing at
http://www.w7ekb.com/glowbugs/rx/Regens/ZL2JJ/zl2jj_trf.htm

My interest is in pictures of what Arnie was describing in his text in
emails.
Pictures of a schematic that mates with pictures of mechanical parts so
I can attempt to replicate known working circuits and the mechanical parts
that just do not exist in my modern world to reference.

Arnie seems a bit techno crippled in that he can not simply snap a picture
and post it to the YAHOO reflector.
It would be much better for all of us trying to learn from great sources
like Arnie
if Arnie COULD take a picture.
I just bought a Android smartphone at Walmart for $20.
It has a great camera in it that takes up close circuit pictures just fine.
I'm thinking its time to mail Arnie a camera... or a dirt cheat
smartphone like this..... that he can
plug into his PC and post pictures on the web....
or at least email pictures to us that WE post on the web for him.
But then Arnie said the mail service is real slow and very unreliable
since I sent 7.16 resonators to him
at the same time I sent 7.16 resonators to UK.
Arnie didn't get his resonators while UK got them in 7 days.

Can anyone recommend a way to get Arnie a camera so he can share his
radios ,schematics...pictures?

ELECTRIC RADIO web page will sell back issues.
I guess I have to buy this issue to get a picture.

HOLA AMIGO!!!
Not that I remember... I saw that very clever variable coupling link
on an article in an old ELECTRIC RADIO US magazine, devoted
to vacuum tube equipment... The photos show how it is built for
a regenerative receiver that uses a 6J5 triode as the detector...
I do not have a scanner.. but maybe it would be possible to take
a photo of the article, if I can locate the ELECTRIC RADIO issue
in my not too well organized library !!!!
So far no message from the post office to go and pick up
something...
It seems likely that soon , after more than 50 years of INCOMMUNICADO
postal services, regular mail will be started between our two
nations...according to a recent joint press release by the Correos de
Cuba and the US Postal Service...
Up to now, all correspondence has to go routed through a third
country !!! And much of it is lost or pilfered in the case of parcels !!!

Rob,

I haven't followed much of this thread and may be covering old ground but here's a web page showing a nice regen with variable link antenna coupling:

< http://www.qsl.net/k7fj/Ultimate%20Regen.html >

Hope this helps...

Or you can try www.nr5q.com. Check out his homebrew radios, and you'll find pictures of a variable link. It's an excellent website and reference. And I believe NR5Q was the author of the article that Arnie cited.

Complete articles about Bruce Vaughn's (NR5Q) "Ultimate Regen" with genius inductive variable antenna coupling you can find in PDF at: regenrx / Files / Tuky FIles / The Ultimate Regenerative Receiver (A Four-Tube (0-V-3) Regenerative Receiver by Bruce Vaughan, NR5Q).

Bruce style of writing is phenomenal.

Regards,
Tuky

Complete articles about Bruce Vaughn's (NR5Q) "Ultimate Regen" with genius inductive variable antenna coupling you can find in PDF at: regenrx / Files / Tuky FIles / The Ultimate Regenerative Receiver (A Four-Tube (0-V-3) Regenerative Receiver by Bruce Vaughan, NR5Q).

Bruce style of writing is phenomenal.

Regards,

Tuky

re: What exactly were you looking for?

PICTURES

Without including all the emails... just sort of nutshell recap....
I may not get it all correct but I think it went like this:
Arnie posted a description of a mechanical linkage that worked for
receivers which gelled into ZL2JJ projects.... pointing at
http://www.w7ekb.com/glowbugs/rx/Regens/ZL2JJ/zl2jj_trf.htm

My interest is in pictures of what Arnie was describing in his text in
emails.
Pictures of a schematic that mates with pictures of mechanical parts so
I can attempt to replicate known working circuits and the mechanical parts
that just do not exist in my modern world to reference.

Arnie seems a bit techno crippled in that he can not simply snap a picture
and post it to the YAHOO reflector.
It would be much better for all of us trying to learn from great sources
like Arnie
if Arnie COULD take a picture.
I just bought a Android smartphone at Walmart for $20.
It has a great camera in it that takes up close circuit pictures just fine.
I'm thinking its time to mail Arnie a camera... or a dirt cheat
smartphone like this..... that he can

plug into his PC and post pictures on the web....
or at least email pictures to us that WE post on the web for him.
But then Arnie said the mail service is real slow and very unreliable
since I sent 7.16 resonators to him
at the same time I sent 7.16 resonators to UK.
Arnie didn't get his resonators while UK got them in 7 days.

Can anyone recommend a way to get Arnie a camera so he can share his
radios ,schematics...pictures?

ELECTRIC RADIO web page will sell back issues.
I guess I have to buy this issue to get a picture.

++
WOW !
I found it.... together , mixed into the stack of SPRAT Magazine, the
G QRP Club publication.
ELECTRIC RADIO
NUMBER 134
JUNE 2000
PAGES 20 TO 27
A WONDERFULLY WELL WRITTEN TECHNICAL ARTICLE ABOUT
REGENERATIVE RECEIVERS....THE 6J5 REGENERATIVE DETECTOR
CIRCUIT THAT THE AUTHOR USES WORKS VERY WELL, WITH
A NICE SMOOTH REGENERATION CONTROL ...
I tried it with a 6C4 and also with half of a 12AU7 * same as 6C4 *
then an attempt to use the 12AT7 / ECC81 did not worked so well
possible to it having a much higher MU * amplification factor "
May I suggest also that all of you download the ZL2JJ Regenerative
Receiver because it a pacesetter of all times, including the
magnificent mechanical construction... The one I built years ago
had newer , but similar vacuum tubes, but my very limited
mechanical abilities, and lack of a machine shop * the two combined
against me * made me dis-assemble my ZL2JJ for recycling some
of the hard to find parts....
73 and DX
Arnie Coro
CO2KK
Host of Dxers Unlimited radio hobby program
Radio Havana Cuba
http://www.radiohc.cu

++
HOLA AMIGO!!!
Not that I remember... I saw that very clever variable coupling link
on an article in an old ELECTRIC RADIO US magazine, devoted
to vacuum tube equipment... The photos show how it is built for
a regenerative receiver that uses a 6J5 triode as the detector...
I do not have a scanner.. but maybe it would be possible to take
a photo of the article, if I can locate the ELECTRIC RADIO issue
in my not too well organized library !!!!

So far no message from the post office to go and pick up
something...
It seems likely that soon , after more than 50 years of INCOMMUNICADO
postal services, regular mail will be started between our two
nations...according to a recent joint press release by the Correos de
Cuba and the US Postal Service...
Up to now, all correspondence has to go routed through a third
country !!! And much of it is lost or pilfered in the case of parcels !!!

Hi Rob,

You're welcome. I always assume that a request like yours comes *after*
a Google attempt that ended in frustration. My search term was "ZL2JJ
regen". You and I know that means the same thing. Unfortunately
computers are dumb as a box of rox! <evil grin> This time I got lucky.

Hi Rob,

You might also look for something called a goniometer. It is a set (pair) of inductors and the coupling is varied by mechanically moving one of the inductors. The ones I have seen have the movable inductor inside the fixed inductor and the movable inductor is rotated to vary the coupling. The movable inductor may have a linkage to a front-panel control unless it is a 'set and forget' part. It may or may not be what you are looking for.

Mailing "stuff" to Arnie.

Some years ago I sent various e-mails to Arnie - but somehow they never arrived in his 'in-box'.
After that I wrote - but the "standard" letters didn't arrive either.

More recently I WAS able to get thru to Arnie's in-box and soon I had a reply - here on Yahoo. Great!
Last week I posted a small packet to Arnie, and I'll advise here, on Yahoo Groups, when he gets it.

Prof Coro is such a well informed and helpful fellow that we are ALL poorer when the communication channel between his place and ours restricts our conversations and packages.

Les

You could use an old varable capacitor with reduction gear, to move the coil. If the plates have a shortcut, just pull them out and you have the complete mechanics already.

Brilliant idea amigos !!!
The Soviet VEF206 receivers have a variable capacitor with I think is
a 6 to 1 reduction ratio.... Ideal for that application
Old Barker and Williamson coils assemblies also had a mechanical
device to move a coupling link in and out of the center section of
a push pull coil..
You can also try to assemble a resistive attenuator pad , with switching
for minus 10 dB, minus 20 dB and minus 30 dB... In actual practice
I have found that the 4 settings are enough... One is bypass, no attenuation
number one minus 10 dB * the most frequently used while scanning
the short wave bands *, and with strong stations go to the minus 20 dB
setting...In my opinion it is always worthwhile to run a grounded grid
RF amplifier ahead of the regenerative detector, and use a very simple
RF attenuation circuit by putting a 5000 ohms variable , good quality
potentiometer between the cathode and ground... Feed the antenna
by means of a capacitor connected to the center of the potentiometer...
That will move the operating point of the triode tube, enough to provide
a certain degree of signal attenuation. BUT, I prefer to combine this
simple RF attenuator with the attenuator pad with the minus 10, minus
20 dB and minus 30 dB attenuation...
When properly adjusted for optimum operating parameters even the
most simple minimum parts count regenerative vacuum tube detector
provides a truly amazing performance... !!!
ADDENDA> A further comment...DC , regulated DC on the filaments
of the detector and the first audio amplifier tube are ESSENTIAL,,,
because they reduce HUM to a minimum and contribute to stability
too...
Second comment.... Some very good tubes are able to provide very
nice reception when you run very low plate and screen voltages...
My practical experience is that changing the plate voltage , and the
screen voltage very carefully further contributes to detector stability
and thus much better CW and SSB reception, as well as reception
of PSK31 and MFSK16 digital modes...

Mike, WU2D, built a very nice 40m "Novice Special" with a moving antenna link and Faraday shield. Have used the moving link in a regen build and like Vaughn's write up about his "Ultimate", it seems to be an important improvment- especially if no RF stage is used. It may be posted in the files section sometime around 2010, or he has a youtoob covering its build and operation, IIRC...

It's on youtube:
https://youtu.be/DVKBKCkmrWI?t=132 https://youtu.be/DVKBKCkmrWI?t=132

Some time ago i tried a similar faraday shield combined with a fixed coil. It eliminates the capacitive coupling and reduces a lot of influences between antenna and preamplifier on the tank circuit.

Here is another example:
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/converter_with_faraday_shield.pdf https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/converter_with_faraday_shield.pdf
The faraday shield is constructed by thin copper wires.
What is the advantage, less eddy currents / losses?

This is an interesting variant. I have used a variometer
with similar effect, however without shielding. I would
think that many attenuator designs feeding a grounded-grid
or grounded-gate RF amp would work well, even better if the
RF amp is shielded. I would start with the time-proven
Newkirk design. Even KISSing with a potentiometer at the
RF input works quite well to optimise the regen response.

My design preference (thus far) would be :
RF attenuator > GG-RFamp > Regen det (or Q-multiplier)
> AF filter (passive or active) > low-noise AF amp.
RF stages can be tube or semiconductor, AF stages
likewise, but I am happy with hybrids using low-noise
silicon AF options :-)

Nowadays, ambient noise is more determinant than
design optimisation. So a screened loop antenna
can be the most significant part of a regen...

How about GG RF Amp coupled to tank by moving coil and regen detector followed by AF string?

Weak signals make it in through a low noise, low gain GG RF amp run wide open (6GK5 or cascoded 6ES8), then attenuation occurs before the detector in a shielded, movable link tank coupler.

Thoughts please?

-geary

Certainly worth a try. I suspect adjusting the moving coil would
require retuning and tweaking the regen, but there might
be an optimal setting for a band segment. An attenuator pot
between aerial and GG RF amp might be indicated to tame
strong signals.

I think that the better solution is variable or fixed attenuation installed _ahead_ of the grounded-grid amplifier, not after.

The grounded-grid amp--one tube only; the gain of a cascoded or cascaded pair is not needed and is actually undesirable) gives you several very desirable characteristics:

1 Low, predictable, mainly resistive input impedance (as a first-order approximation, 1/transconductance, which for the 6GK5 (transconductance, 15 mS) equates to an input impedance of 67 ohms--a good match for a 50- to 75-ohm antenna system). This lets you design and install--between antenna and grounded-grid stage--known values of frequency-independent attenuation that can be easily implemented with carbon-film resistors. Or play a bit looser with impedance matching and install a low-value potentiometer--say, 500 ohms--for continuously variable attenuation.

2 Good buffering of the detector from impedance variations, including attenuation adjustments, on the low-impedance antenna-input line. Adjustable coupling right at the detector tuned circuit via affect the detector in profound ways _and_ give results that will vary with frequency.

3 Good suppression of feedthrough from detector to antenna.

Varying the detector's signal diet by inserting attenuation and/or filtering _ahead_ of the grounded-grid amplifier also makes the amplifier more overload-resistant in a way that adding post-amplifier attenuation cannot. Assuming a well-behaved amplifier, every dB of attenuation added ahead of the amplifier decreases 2nd-order intermodulation distortion products in that amplifier by 2 dB, and third-order IMD products by 3 dB.

The circuits in my page at http://dpnwritings.nfshost.com/ej/wr/ illustrate this technique, which also works well at IF. At 40 meters I'm using about 18 dB of attenuation between the antenna and grounded-grid stage such that the antenna-system noise floor _just_, but clearly, overrides the receiver's internal noise floor. The receiver is so resistant to pulling and overload by strong signals that I may not have to touch its REGENERATION control across multiple operating sessions.

I just uploaded the schemo's of my Mk.14 & 15. As usual, I don't bother with coil data because that can be determined by the selection of the coil/varicap combo. For the faint of heart I've grounded the chassis, but that only works if the set is plugged into a properly grounded outlet. While it's not foolproof, it shoukd be safe enough for non-fools. I tried to come up with a circuit that would use a SPST relay effectively but it obviously came up short. Also, since the AC switch is on the audio gain control, I put it as close to ground as I could to reduce hum. The only hum I get now is from the output tube being powered from the filter input. I can live with it because I can hardly hear it.

From: nzerowva@...
Topic: 25941 Message: 25941

Added some photos. Homebrewed another regen, this time tried a tube. Works good, buch for SSB and CW, transistors behave better, but the triode seems to be better at detecting AM, although it does load the tuned circuit a lot more. Not sure if its the extra tickler turns or maybe lower input impedance doing that.

I used to not like to use those superhetrodyne variable capacitors because of the extra gang, but I am finding out you can use it to your advantage by making the small section tune the SW bands, and using the large section to tune the BCB plug in coil. Works pretty good.

I am wondering about substituting FETs in some of my tubed regens. I kind of wish you would define a little more specifically what you

mean by “behave better” or “better at detecting AM”.
I assume “behave” might mean stabililty.

I’d guess the “better at AM” means more audio recovered.

About the tuned circuit loading, i’d guess that means skirt selectivity, meaning more effect of strong signals spaced from the one you’re

tuned to.

Some of those old classic project articles used multi-pin coil sockets with wiring inside to select the section of the variable, either the large

section or small section, as you point out, for the different freq regions.

Its hard to explain, but the actual AM detection seems to be better in that the gain acts like it is higher and in a broader region just before oscillation. And seems just the opposite when in the oscillating condition (the FET has more gain). Maybe it is just me.

That's quite possible, as vacuum tubes and FETs--in this case, JFETs, I think, which will behave somewhat differently than MOSFETs because there can be no gate-source conduction in a MOSFET without destroying the device--are very, very different devices. The current flow in both is controlled by the electric field surrounding its control element (grid or gate), but once there's conduction through that control element their behavior can be expected to diverge.

Dear amigos :
Question:
Would it not be better to have the 500 k volume control
at the grid of the first 12AX7 triode ?
Or should it be placed between the first and the second triode,
replacing the 470 k grid resistor ?
There is A LOT OF GAIN available from those two
triodes 12AX7 feeding into the 50C5
My favorites audio tail ends are two:
One ? a la Collins ? a copy of the audio section of the
75A1 receiver
Two the classic ECL82/6BM8 that works very well too
Of course that there are many possible circuit diagrams
for the audio tail of a vacuum tubes regenerative...
as virtually any of the many tubes available can be used.
The power for those audio tails, and the regenerative
detector etc, can be easily be produced by two back
to back 120 /12.6 volts transformers... and you will
be protected from possible AC power line shocks that
may come from using the power line without a
transformer !!!

Hi all,
I just bought this old crystal set on Ebay Can anyone tell me what it is called, when it was popular and why does it have two tuning coils? I bought the one without the black knobs.

Thanks Dan W3DKY

Hi All,
I just purchased this set of Fada Neutradyne caps and coils. Can someone tell me which would be the best schematic to use these in.
Thanks

I think the high gain of the 12AX7 makes it more likely to pick up hum, especially if the AC power switch is mounted on the audio gain control. Putting it in the last stage seems to help a lot. I try to keep the high gain circuit leads as short as posible. Also, putting the power switch in the ground side of the circuit helps too. I suspect that's why so many AA5 receivers have the power switch on the ground side of the circuit.

I favor the cathode control to control the RF amp gain because the gain control can be mounted anywhere. The antenna input control has to be mounted as close to the RF amp circuit as posible, with an extended shaft or sheilded leads.

My safety relay circuit is not totally practical because it would not work with a GFI. The ground current would trip the breaker. I never liked the idea of hooking up two transformers back to back to isolate the circuit from the AC line. I have isolation transformers for that purpose, one 5A in my bench and a 15KVA supplying most of my other receivers. I find them more useful for cutting down line noise. I found this out with my R-649A. It had an anoying hum until I put it on a small isolation transformer. But even with a transformer, 120 volts is still 120 volts. I think the best safety device for electrical work is a healthy respect for electricity, not fear.

Leonard

Dear amigos :
Question:
Would it not be better to have the 500 k volume control
at the grid of the first 12AX7 triode ?
Or should it be placed between the first and the second triode, replacing the 470 k grid resistor ?
There is A LOT OF GAIN available from those two
triodes 12AX7 feeding into the 50C5
My favorites audio tail ends are two:
One ¨ a la Collins ¨ a copy of the audio section of the
75A1 receiver
Two the classic ECL82/6BM8 that works very well too
Of course that there are many possible circuit diagrams
for the audio tail of a vacuum tubes regenerative...
as virtually any of the many tubes available can be used.
The power for those audio tails, and the regenerative
detector etc, can be easily be produced by two back
to back 120 /12.6 volts transformers... and you will
be protected from possible AC power line shocks that

may come from using the power line without a
transformer !!!

Hi Leonard,

The question of the deadly AC/DC or not has been brought up many times on many radio lists. I am pretty much in agreement with *your* view but would like to add -

If you are afraid of the electricity you should just stay away from it. Being fearful will probably get you hurt or worse. Healthy respect and using safety procedures will allow us to enjoy. There is no room when working with the power line for laying 'hot' chassis on your lap or just grabbing it any which way. It's a whole other ballgame. Some of us were fortunate to have good coaches in that kind of ballgame when were young. The rest should limit themselves to single 9 volt batteries (not series stacks). Even 12 volt car batteries can hurt you very badly.

Laying back in the tub of hot water while listening to the AA5 on the edge of the tub - *NOT*.

73,

Bill KU8H

Leonard,

Beautifully presented schematic! The old world used to
prioritise top-edge HT line, bottom-edge ground line
and left-to-right signal path. Many new-age schematics
follow an inscrutably superior neo-logic, which confounds me...
My Dad was one of the youngest licenced hams, worked
in hush-hush WW2 research, built one of the earliest
Nipkow TV receivers (which should never have been junked).
So I guess I am in genetic synaptic brain-warp...

If I had the bits, I would love to replicate your designs.
I am slowly collecting old AM radios, so perchance, one day...

Michael

One thing I forgot to mention, the cascode RF amp I use on many of my projects. It is supposed to be less noisy than a pentode amp, but that may be lost on my set because of other problems. Also, it has the feature of a grounded grid with added gain. In this case the calculated gain is about 30. I've also tried a cathode coupled RF amp but results were not sensational. Another thing I didn't mention was that the Mk.14 uses plugin coils. I wound two sets of 4 pin coils for 7 bands, which is why the Hartley detector is not used. The Mk.15 uses a set of slug tuned coils I found in my junk box. There was just one set of coils so I had to use an untuned RF stage. Meanwhile, fun continues non-stop.

Michael,

I'm with you on the schematics. Back then they were laid out like railroad tracks (that's why the power lines are called "rails"). If you observe, the B+ and ground lines are the rails and the circuits between them are the ties. You can consider the signal path as the third rail. The train goes down the track from left to right (East to West). It makes sense, and once you learn it reading schematics laid out in that form are simple. Even complex circuits are easy to read and can be taken in as a whole in a glance. I'm an old fart and I built my first crystal set back in 1947. Electronics was my working career and I taught it for close to 30 years during that career.

I agree, Jim. I built my first Xtal set in 1942. Power at the bottom of the diagram was what I lesrned first from reading old Audel's manuals. I can certainly see the practicality of the "rail" system, and I notice it's more prominemt in SS circuits. Old habits are hard to bresk, but I'll try to force myself to comply in the future.

Good point, Leonard; however, port to starboard cannot take compass points in consideration. My mind was conditioned on compass directions with North being up. I'm a confirmed landlubber. ;-)

Avast there, I won't hold that against ya. Most of my carreer was being in and working for the Navy. All our schematics were power from the bottom up. That's probably why it's a hard habit to break. But I think as long as appropriate labeling is used, confusion should be minimal.

This is a beauty :)
But while it probably could
be used as a crystal set, I'm
more inclined to believe it is
a combination wave trap and
selective frequency pass band
thingie :)

If I am correct, you'd use it before
the crystal set to block out a stronger
signal that inter fears with the frequency
you are aiming to listen to, or just a general
pass band to filter out any and all signals
that are above or below your target frequency.

The person that built this took care and
looks like they knew what they wanted and
did a good job with it.

OK, my first guess, who else might know
about this item.

Interesting! A crystal set that picks up stations without a crystal! I also reached the conclusion that it was a wave trap of sorts. Mike, W6MAB

OK, sounds good :)
I did not see a crystal, but then
again it would be easy to hide
in those pictures…

It does look like a nice set, and
again, well built. Now that you
have it, does it look like it might
have been from a factory, or does
it look to you to be home made.

If it was home made, they sure
did a bang up job with it :)

I was hoping someone else would
have chimed in by now. Maybe
shortly someone will enlighten
me/us. Thanks for taking or sharing
those pictures, I did save them :)

Reducing gain sooner is generally better than reducing gain later from a stage-overload point of view. That is, in a detector-AF-AF lineup, if you put the AF GAIN control between the two AF stages, AF output from the detector may overload the first AF stage, and no gain reduction by means of the AF GAIN control will be able to help. So from a gain-distribution point of view, making the AF GAIN control the grid resistor of the first AF stage is better.

That said, however, those still using ac on their tube heaters may find that with the AF GAIN control in the grid of the first stage, hum in the first stage may be objectionable by the time it's amplified by the entire AF chain, and turning down an AF GAIN control in the grid of the first tube in the chain won't help. In this case, putting the AF GAIN control between the two AF stages will maximize signal-to-hum ratio.

Ac hum from ac heater supply is, of course, a self-inflicted problem. It's 2016 and well-filtered, high-current dc sources abound. Using dc heater supply gives you more options, like being able to put the AF GAIN control in the grid of the first stage without regard to signal-to-hum ratio.

Putting the AF GAIN control between the two AF stages may also better hide motorboating problems. (Motorboating is when two or more tubes in the AF chain oscillate at a subaudio rate as a result of interstage coupling via the B+ line. The result is a sound like a motorboat from Central Casting.) If your receiver motorboats, you need to add decoupling in the B+ lines to one or more stages, beginning with the B+ line to the detector. I generally use a decoupling resistance of 1/20 or 1/10 the value of the plate load resistor, with a large capacitance (47 to 330 uF) connected to common from their junction. You should be able to turn up your radio's AF GAIN control all the way--with REGENERATION turned up as far as you ever will during normal operation--without motorboating.

Best regards,

Dave

Muchas gracias... Thanks a lot amigo Dave for the
very well written analysis...Two 12AX7 triodes provide
a lot of gain, and you can introduce,with proper
switching, some type of audio filter, like ZL2JJ did
with his wonderful receiver.
Whenever possible it is a very good and nowadays
rather easy to implement idea to use regulated
DC on all the filaments of the vacuum tubes receivers...
Now back to the garage workshop where I am going
through many boxes where recycled parts are in
random storage (my fault), so paying the price to
go through all those boxes to find the parts to assemble
the receiver using the ceramic resonators for 40 meters...
then afterward will try to build a VFO using the same
type of resonators that are blue and have three legs...
73 and DX
Arnie
CO2KK
BTW; This morning checking on the two Cuban national
40 meters band nets, SSB and CW, propagation was
rather good... worked many stations on 7110 and 7115 kHz , and also
heard several USA CW stations rather
late in the morning... We are now, here in Cuba on
Eastern Daylight Saving Time 4 hours away from UTC

Very informative. Putting the power switch on the ground side of the supply seems to help reduce the hum. Keeping the AC leads away from the audio grids helps too.

If the bias battery is really necessary, i'd go with it. But my thought is, use a PNP audio transistor and a single battery. A voltage divider off the -9 battery with a zener diode for regulation. I think the combination of this with the lytic cap 9 volt bypass should ("should") smooth out all audio voltage from the 9 volt supply so that SSB and CW reception does not warble.
This circuit is like the "new Doerle" (2 type 30 tube) going on 75 years later. Even the pot is reminiscent, as the old tube Doerles had a filament adjustment rheostat.

If by this you mean putting the power switch in the ac neutral lead rather than in the ac hot lead, maybe that could lead to less-hummy operation, but it's also less safe. We want our power switch to break the ac _hot_ lead; if we break only the neutral, the hot connection is still connected to the circuit to be powered, and only a fault (say, an internal short to chassis inside the power transformer, or a shorted neutral-to-chassis bypass capacitor between the switch and transformer) is necessary to set up a dangerous situation. A fuse or circuit breaker should break hot, not neutral, for the same reason.

I use a relay to break the hot side. The control switch is on the neutral side of the relay. Nothing gets to the chassis (except ground) unless the switch is closed. However, the setup is not foolproof. A 9 volt guy could still get zapped.

If by this you mean putting the power switch in the ac neutral lead rather than in the ac hot lead, maybe that could lead to less-hummy operation, but it's also less safe. We want our power switch to break the ac _hot_ lead; if we break only the neutral, the hot connection is still connected to the circuit to be powered, and only a fault (say, an internal short to chassis inside the power transformer, or a shorted neutral-to-chassis bypass capacitor between the switch and transformer) is necessary to set up a dangerous situation. A fuse or circuit breaker should break hot, not neutral, for the same reason.

Best regards,

Dave

Actually, the whole idea of my "safety" circuit is to prevent the chassis
from being connected to the hot side if the outlet is wired backwards. The
fuse is to protect the line, not the radio.

Hi Leonard,

One means I learned years ago for testing a 9 volt battery involves self-zapping. It's not recommended and I rarely do it..I have a small load and voltmeter to test them these days. I don't know how much current a fresh 9 volt battery will provide but I don't think I would want one in my jeans pocket shorting through a quarter or a dime! If we start building series stacks of those they will impress. Some of us take a "low dose" (81mg) aspirin each morning to protect hearts that are 'at risk'. Those little aspirins don't do a whole lot dose by dose. If you take the whole bottle full at once you will be in deep trouble. It's the same with "harmless" low voltage/low current batteries and single high current batteries. Again - the safety procedures apply. I have considered building an AC/DC radio and I would wire it to reduce the chances for having a hot chassis from a non-polarized plug. But I evolved my preferences to batteries before I got a round tuit. It's still not risk free. It just eliminates a source of hum and does not depend on the unreliable electric utility.

For a safer hobby try learning to play an acoustic musical instrument. There is no electricity involved so no shock danger. However some of them are heavy and could break small bones if they get dropped on your foot. Maybe best for some people to just stay in bed. <evil grin>

It really doesn't harm anybody to point out the dangers anywhere. At the same time we should point out there are procedures and means to reduce the risks to something 'normal'. Normal being equal or less than all the risks we face daily just getting out of bed (or even staying in bed).

Yours for safely *enjoying* the hobby.

Bill – i’m retired from an ILEC (“incumbent local exchange carrier”) phone company.

Some of the outside techs used to check 9 volt batts that way, but it was never to my “taste”.

As for the current from a 9 volt batt, the max current is limited by the internal resistance of

the battery, of course, but it will drive a couple amps for sure. I tried this once, and it will

light up a wire shorting it. But only one time, then the batt’s dead & gone. I was just interested

to see if a 9 volt battery could be used to fire something, like a rocket or glow plug engine or

whatever, just an experiment.

When I was a kid (and Noah was still building his Ark) batteries were scarce. Money was even scarcer, so batteries were not high on the list of options. I tried making my own batteries without much success. AC power was the only answer. You learn pretty quickly what not to do when woeking with 110 volts (as was the line voltage back then) Actually, driving a car is far more dangerous, especially if you live in Honolulu.

Congratulations amigo for the family now ready
to grow !
I think about two or three of the 500 e'mail messages
came from yours truly
Thanks a lot for keeping up our interest in the science
and magic of regenerative receivers....
Now working on a new one that, yes, uses three legged
blue ceramic resonators for 40 meters !
After the first test, I am now sure that several 500
kiloHertz electromechanical filters that lacked the
matching quartz crystal for the carrier oscillator may
be brought back to useful like by using 500 kiloHertz
ceramic piezoelectric resonators !!!
One good idea is always followed by several other
new ones !!!
Thanks a lot amigo Rob

Um, Bill, I wasn't talking about _transformer_ lead color, but the colors of the mains wiring in the house and at the cordset relative to wiring-color conventions common in electronics, according to which latter convention black is usually chassis/negative (and therefore "safe").

As discussed in this forum some time ago, I've lived the "switch in one wire, breaker in the other wire, hot fault to chassis with a nonpolarized plug" scenario with an HW-16 ham transceiver and it was only by luck that I wasn't injured.

As no less than Horowitz and Hill in _The Art of Electronics_ write, "Never build an instrument to run off the power line with a transformer! To so is to flirt with disaster. Transformerless power supplies, which are popular in some consumer electronics (radios and televisions, particularly) because they're cheap, put the circuit at high voltage with respect to external ground (water pipes, etc.). This has no place in instruments intended to interconnect with any other equipment and should always be avoided."

So _of course_ I wouldn't be writing with respect to transformerless operation, because I don't respect it at all..

Best regards,

Dave

Hello all,

I am looking at some older projects from the late 60s, early 70s where germanium transistor were used. Assuming the gain of is the same, can I simply plug a silicon PNP for the germanium PNP transistor, without any circuit mods. The first project is a simple side tone monitor Osc. that can be added to a tube transmitter.

Thank you,

Robert

Well, it depends. The bias settings for a germanium transistor is a bit different from a silicon transistor. Seeing as how a germanium junction takes about 0.3 or 0.45 volts to overcome, and a silicon junction takes about 0.5 to 0.7 volts.

If the transistor is used as a switch, then it probably doesn't make much difference, but if it is a class A amplifier, like a typical audio stage, then you will probably have to reset the bias. For a momentary test, you can probably get by without doing this, but long term use would benefit from resetting the bias levels.

If the oscillator in this case is a blocking type oscillator, probably no problem, but a sine-wave oscillator will probably suffer waveform distortion unless the bias is optimized. The best answer is "try it and see". You won't damage anything, the worst that can happen is the oscillator either won't start, or it will sound bad. And unlike years past, transistors nowadays are so cheap that you won't be out more than a few pennies if it blows up.

If you have access to an oscilloscope, use it to explore the output waveform as you make adjustments to the various resistors in the circuit. Don't change any of them more than 50% in value while doing these tests. If a change makes the circuit work better, either when starting or when running, then go ahead and use the new value(s).

Remember of course to take into account the different in supply voltages needed for between PNP and NPN circuitry.

No, at the very least they would require reworking the base bias
circuits. Silly-cone devices drop approximately .6 Volts across the
emitter/base junction. Germanium devices want to see something on the
order of .2 to .3 Volts bias. That would also mean having to rework any
AVC/AGC circuits. Of course a sidetone oscillator doesn't have AVC/AGC,
but you would still have to rework any bias circuits. . .

From a 3-color line cord perspective (120VAC, 60Hz), BLACK is HOT, WHITE is NEUTRAL, GREEN is Chassis Ground.

On a 2-wire Line Cord, the WIDE lug is NEUTRAL. _All bets are off on an older 2-wire Line Cord with equal width lugs_ as there is no key to ensure correct "polarity" with the outlet.

The NEUTRAL lead is ground referenced back _at the distribution panel_ (not at the outlet!). This will ensure the chassis is not HOT if what's behind the wall is wired correctly. A quick test is to measure voltage between the wide lug (3-prong outlet) to the screw in the middle. It should read near zero volts.

73,
kevin
kc6pob

Bill, I wasn't talking about _transformer_ lead color,
but the colors of the mains wiring in the house and at the
cordset relative to wiring-color conventions common in
electronics, according to which latter convention black is
usually chassis/negative (and therefore
"safe").

Dear amigos:

Biasing the gate of a FET from a separate power supply
in this case, just another 9 volts battery seems to
produce a very marked improvement of the regenerative
detector when that bias voltage is carefully changed
while observing the performance of the receiver.
I will try to determine if the 9 volts bias battery is
really required , or it can be replaced by a 3 volts
lithium cell....
Any comments from anyone building this design
will be most appreciated... FETs and MOSFETs are
not available locally here, so I tested the circuit
using a FET removed from a computer motherboard
for which the datasheet is not available !!!
Also I am interested in the use of the transistors
that can be recycled from compact fluorescent light
bulbs for audio amplification. AA1TJ Mike already
produced a receiver using those transistors !!!

I use IEC connectors on most of my projects so one line cord fits all. Some time ago I bought a bunch of connectors that were made in UK I think, because they were color coded for 220VAC, but they still work on 120VAC. It just takes some ringing out to get the right polarity.

Leonard

I suggested changing the second transistor to a PNP, to be able to use only
one battery, and of course i missed that the FET still requires
B+, so this is wrong, not a solution.
It did occur to me to use a zener or LED in the FET source-to-ground, with a
pot and bypass cap across this; the wiper of the pot going to
the FET gate. The FET current might not be enough to keep the zener or LED
in its ideal working zone, so a resistor from the B+ to the
FET source might provide a little more current through the bias component.

Another thing to remember when comparing germanium to silicon is that many germanium circuits were self biased by the inherently leaky germanium junction. In subbing a silicon device that bias must be supplied.

Paul

>
> Well, it depends. The bias settings for a germanium transistor is a bit different from a silicon transistor. Seeing as how a germanium junction takes about 0.3 or 0.45 volts to overcome, and a silicon junction takes about 0.5 to 0.7 volts.
>
> If the transistor is used as a switch, then it probably doesn't make much difference, but if it is a class A amplifier, like a typical audio stage, then you will probably have to reset the bias. For a momentary test, you can probably get by without doing this, but long term use would benefit from resetting the bias levels.
>
> If the oscillator in this case is a blocking type oscillator, probably no problem, but a sine-wave oscillator will probably suffer waveform distortion unless the bias is optimized. The best answer is "try it and see". You won't damage anything, the worst that can happen is the oscillator either won't start, or it will sound bad. And unlike years past, transistors nowadays are so cheap that you won't be out more than a few pennies if it blows up.
>
> If you have access to an oscilloscope, use it to explore the output waveform as you make adjustments to the various resistors in the circuit. Don't change any of them more than 50% in value while doing these tests. If a change makes the circuit work better, either when starting or when running, then go ahead and use the new value(s).
>
> Remember of course to take into account the different in supply voltages needed for between PNP and NPN circuitry.

Its been my experience that with a straight regen (no rf amp) that what works the best as a general rule of thumb is adjustable capacitive coupling for anything below about 2.5 mhz. Anything higher in frequency link coupling seems to work fine, even if you using a "long wire". With resonant antennas, again link coupling works the best due to lower impedances, but usually one turn and very light coupling.

Hue,

The green LED does work best out of all the colors, no need to jump it with a capacitor, I found very little difference, if any in operation. If your power supply is adjustable, you can vary the drain voltage to get it to work the best. The green LED worked best for me at 12 to 18 volts.

Arnie said that he has UNOBTANIUM class parts.... FETs
MOSFETs...NE602..... AUDIO ICs.. etc.
BUT
things change fast with the brand new embargo and postal laws so I
suggested that we track down some
penny parts on EBAY and Arnie said he never used and is unfamiliar with
EBAY.....
so I figured I would show an example of how cheap, easy and simple it is
to go to EBAY and spend $10.60 on
1,000 transistors.
http://www.learnmorsecode.com/ebay/index.html

2N7000 MOSFETs cost 10 cents now.

I spent $300 on 10,000 various components last year and now just about
anything I find a schematic for is fair game
without waiting for an obscure part ...like a J310 .... to arrive in the
mail.
Unless of course it is an obscure part I don't have yet like a PNP
germanium transistor.....
but I expect to have them in a week or two.

Hello all and Hola Señor Arnie
First posting to the group but I really the discussion on the regenny rx - and regarding germanium transistors, is there a preferred and quick way to test - I do not have a curve tracer. Reason for asking is I acquired a small container full of early 60's vintage Western Electric transistors (and some gold plated hybrid integrated circuit can's that came from a SAGE computer) - I was originally going to test these out for friends who build guitar fuzz pedals but these could show promise in a RF circuit.73Mike AA9IL

I can confirm your translation is correct.

I have cyrillic script on this PC BUT it only present PRINTEDcharacters.
BUT - with a few clues help. First the characters you see as "m" are Russian SCRIPT characters for "T"

26035. Re: Substituting Ge Xstrs

Yahoo group: regenrx (2016 — 2017)
Date: 2016-03-17 01:11:32 UTC
From: les.au49@...
Topic: 26020 Message: 26035

I confirm your transliteration is correct. The letter that appear as "m" is Russian script for "t".
But the printed "M" transliterates to Latin/English "m". So EMummep -> Emitter. However, in printed characters the Latin "T" is simply "T", not "m". The KGB did this to confuse the CIA. (!!!)

The word, Korpus is "body".

"P" is the Greek rho, or "R"
"pi" - two uprights with a lintel is "P" - as in "pi".

With that info: baza, eMummep and Kollektor drop out easily. The "Л" is "lambda" or "L"
So Коллектор -> collector.

Russian is a beautiful language, very symmetrical and once the alphabet and a few rules are known the rest is plain memory. There are 32 or 33 characters in the Russian alphabet. The great advantage of this is that Russian text uses a single character to represent sounds English must represent by several. e.g. in kitchen the "ch" sound is represented by the single Russian by ч. And the backwards "R" (i.e. Я) is the first sound in "yard".

The Cyrillic characters will only appear on screens where a Cyrillic script is available. Now I'll see whether the Cyrillic fonts make it thru to your screen!

Les

Thanks for the offer but hang on to your Ge PNPs.
I dabble with simple electronics circuits for radio with the goal being that
I can kit a pile of them and pass them on to scouts and my local radio club.
So when I buy into a circuit I try to come up with 50 to a 100 components
from one source.
This has worked out pretty well... even with UNOBTANIUM parts like 1N34A
catwhisker diodes
which I sourced 1,000 of them from Bulgaria last year for pennies, not
dollars, for each diode.
So if I give away 100 crystal radios once a year for the next 10 years I
have the parts.

I found that when I tried to buy 1N34A diodes in bulk I received
silicon 1N60 diodes.
Hundreds of them from sources saying they were germanium.
Its a language barrier problem somewhere.
Its the only component I got the wrong part... more than once, out of
hundreds of different components
I bought last year.
So when these germanium transistors arrive I will get to play with a
repeatable and sharable
circuit.

Just a curiosity here..... tag-strips... terminal strips.....
I have a bunch of old stock that has a few different kinds of metal in them.
None are rusting or tarnished.
What kind of metal did they make the tags out of?
I want to replace a broken tag in a phenolic base so I was considering
using sheet brass.... just because it bends just enough to play with it.
I figured once soldered it all is just a blob anyway.

Rob,
The 1N60 is a germanium diode, Not silicon. The characteristics are almost the same as the 1N34A. The main difference is that the 1N34A is a point contact germanium diode and the 1N60 is a gold-bonded contact germanium diode. In most cases the 1N60 can be substituted for the 1N34A.

Well I have started on it. I have to if the transistors mounted, and pads in place for the other two. I had planned to work on it last night, but three martinis and a rock concert kind of hindered any progress.

I have this weekend off, so will work on it. This is my first Manhattan construction project, so I may be building this in a larger layout than is needed. Pictures to follow.

I need a little help. I have looked at various tutorials, but they all assume a lot, or do not explain some things.

How do calculate the value of Rb in the "better side tone oscillator? I know Rc is chosen to drop 1/2 of VCC.

Thank you,

Robert

Check out this picture of four diodes.
http://www.learnmorsecode.com/help/diodes.jpg

The goal was to buy 100 1N34A diodes to donate to a kids
gig....Community Safety Day...last May.
I figured parts were pennies so I wanted to donate 100 crystal radios to
the educational cause.
I bought a hundred diodes on a sale titled 1N34A germanium diodes on EBAY.
The diodes arrived and they were definitely not catwhisker diodes.
They are marked "A" in the picture.

I bought other 100 diode batches that had black and blue and green
stripes and no markings
printed on them. They looked like silicon diodes to me. All frauds....
sales titled 1N34A germanium diodes.
So just out of curiosity I bought a sale titled 1N60 germanium diode and
again I got the green stripe diode
the same as the "A" diode.

Then forum wizards told me to buy from
https://www.mikeselectronicparts.com
so I bought the 1N60 diodes marked "B" in the picture.
They were germanium catwhisker diodes.
But they cost 45 cents each and that cost adds up fast when you want to
buy a 1,000 diodes so
I kept hammering the EBAY sales until I found a Bulgarian source that
was 2AA113 diodes....marked "C"
in the picture that sold for a nickel per diode.

So just for giggles I bought 1N60P diodes ..."D" in the
picture......and they were marked 1N60P.
That sort of etched in stone the fact that the green stripe fraud diodes
were 1N60P silicon diodes.

I'm not an electrical engineer with a test bench that can tell me WHAT
the unmarked diodes are so
my one and only test was to place the diodes into the circuit in my
crystal radio.
The tiny diodes were stone dead quiet.
All of the catwhisker diodes played loud and clear AM broadcast radio
stations unless they were physically defective with
the cat whisker not maker contact with the flat plate of germanium.

As I collected this stash of diodes I was told that I can bias the
silicon diodes with one AA battery and they will come to
life and receive AM radio.

So I experimented with a dozen different diodes and received broadcast
radio stations from around the world
with 1N4148 diodes.
It was a very interesting learning experience which sent me down the
regenerative receiver path
because I wanted to know more about HOW this worked, not just build
receivers.

http://www.learnmorsecode.com/help/xtal1.html

So when I said I received silicon 1N60 diodes I think I should have said
that I received silicon 1N60P diodes and that was
fraudulent sales baited by the titled 1N34A diodes.

Rob,
I would say those diodes in picture "A", and all similar, are silicon diodes either 1N914, or similar type of silicon switching diode. Just misrepresented by the seller, or mislabeled by the manufacturer.

If you want to play around with computer logic circuits (AND and OR gates) these can be used to make those circuits and give a good understanding of how they work. They can also be used in place of mechanical switches to switch coils in and out of the circuit for the regenerative receivers. So the purchase isn't a total loss.

Rob,
I was going to mention that the BAT41 Small Signal Schottky Diode is a very good substitute for the IN34A germanium diode. It has better specs, and it's price is low, but the SEND key got in too fast. Do a search on this diode.

From: les.au49@...
Topic: 26045 Message: 26045

A key characteristic of the 1N34A germanium diode is the low forward voltage drop and reverse capacitance (1pF - according to the spec sheet.) The only Schottky diode with comparable reverse capacitance is the BAT41 (2pF).

The other members of the BAT family have a higher reverse "C" - up to 10pF.
I couldn't find the forward voltage drop for a germanium point contact diode at a low current - the figure given for 200mA is 1V and we know it's less than that at 1mA. Looking at the datasheets for the BATnn devices, the lowest forward voltage drop is in the order of 300mV at 1 mA.

More datasheets (and the diodes themselves) are found at Futurlec - http://www.Futurlec.com http://www.Futurlec.com
Just use the search box at the top left to find an item of interest.
I've bought components from Futurlec for many years. Sometimes they mix up an order - and they aren't always fast, but they will always sort out any problem.

I renamed this thread to reflect the topic better.

Les

Also, take a look at the 1N5711 Schottky signal diode.

1N5711 diodes make an acceptable replacement for the 1N34A. They feature low capacitance (2 pF or less), low forward drop (0.1 to 0.4 volts depending on various factors), are readily available from Mouser and other vendors, and are relatively inexpensive. They are also very fast, suitable for use as UHF detectors. I have used them successfully as replacements in the front-end mixer of a -hp- spectrum analyzer (don't ask why I know this!) They also perform well as the detector for a "crystal" radio.

Less than 50 cents each in single quantities, less than 12 cents each in 100's.

- Jim, KL7CC

Well done Jim - and I WON'T ask how you know they work well in HP spectrum analyzers!

At Futurlec (notice the absent "e" they are $0.10 each. I always buy a few dozen so the packer doesn't get bored walking to the parts drawer!

Topic: 26045 Message: 26048

Yes... I did get to experiment with an array of Schottky diodes in my
search for
a cheap 1N34A replacement last year.
This:
Match box crystal radio by Billy Cheung
https://www.youtube.com/watch?v=_7of69KW-JM
uses
1SS106 diodes.

Once I heard them receive on the simple crystal radio I also bought
the SMD versions of them and others.. 1N5711......
because I wanted to showNtell the scouts that what started as a cat
whisker rock detector
and oatmeal box size coil ......COULD be miniaturized into a JAMES BOND 007
package the size of a bottle cap using molded inductors and an SMD 1N5711.
It truly was a learning experience for me that led to the conclusion
that YES we can build crystal radios for pennies for the kids.... and
for $2 when
adding the LM386 amplifier boards to drive magnetic ear buds or headphones.
Air tuning capacitors and crystal ear phones became the cost prohibitive
parts
so I got past the air cap cost with home brew air caps.... just some
artsNcrafts tin foil
and wax paper.

All in all the mission was one of inspiration for the kids to want to
play with radio electronics
while at the same time the parents not getting bitten by a high price tag.
Show a parent a $3 toy that keeps a kid busy with science
or
show a parent a $100 video game
and you can bet they buy into science over gaming... especially when
they only have $20 in their pocket.
So I figured that if our radio club donated to the educational cause and
gave away cheap radios then
we might inspire some kids to do more.
When the parents then go look to buy short wave radios and see $1,000
price tags then
we show them how to build regenerative receivers with their kids and
really hear the world.

Les – i’m glad you gave the reverse capacitance of the diodes also. That reminded me that this may be something to keep in mind

for HF detectors. At 10 MHz for example, a mere 1 pF is about 15,000 ohms equivalent; while only 5 pF is all the way down to around

3000 ohms.

From: Daniel Donnelly
Topic: 26054 Message: 26054

I recently acquired a Sencore Harmonic Gen. HG 104 without the batteries. Nothing was marked on the battery holder and the instruction book does not have a a drawing or define which end of the battery holder is positive. Could someone please tell me the correct battery polarity to connect to the power switch?
Thanks
Dan

The KRC-2 shortwave regenerative receiver kit
<http://feedproxy.google.com/%7Er/TheSwlingPost/%7E3/uRX79fL9W6Q/?utm_source=feedburner&utm_medium=email>

Posted: 28 Mar 2016 09:52 AM PDT

Tony Westbrook recently contacted me about a regenerative receiver kit he has designed and produced in the UK. It's called the KRC-2 <http://www.kitradio.co.uk/page10.htm>. Here's the product description:

/1 – 30 MHz with band spread tuning./

/Regeneration with a difference. The regeneration setting on the KRC-2 is unaffected by the receiver tuning or the antenna coupling. How do we achieve this? The regenerative stage is fixed at 10.7MHz and used as an IF amplifier. The main receiver board is extremely simple to construct using only one FET and an audio IC. Like all the KRC kits it comes with a comprehensive construction manual which brings this project well within the grasp of the keen constructor. It was referred to as "a very sensitive little receiver" by Rob Mannion of Practical Wireless. Its unconventional design and simplicity should amaze even the experienced constructor. Case size 7 x 4 x 3 inches. 6 x AA batteries supplied./

According to Tony, the kit comes with everything; UK orders are even supplied with batteries. Tony stated, "the only thing the customer needs is a soldering iron, solder cutters, etc."

By request, Tony sent a few construction photos and three videos of the radio in operation:

From: Leonard Meek
Topic: 26058 Message: 26058

I just uploaded an update of my Mk.23 regenodyne.It's still pretty much the same except for some component values. Note the 1 Meg plate load resistor in the detector. That came by cut & try. It gave the most gain, but I'll probably find out at what cost later. I changed the osc/buffer to a 12AU7. It fit the calculations better and gave a much smoother output. Following Dave's and Prof. Coro's recommendations, I moved the AF gain control to the 2nd audio stage. I feel confident enough now to tackle a really BIG regenodyne project.

Hey, thanks Arnie, for posting this. I have been thinking about this one for about ten years.

The photos and vids on the links you sent are better and more informative than those on

Kit Radio Company’s own site.

The exhange rate UKP: dollars is rather high, so the radio is not a bargain price item here,

compared to that kit offered in the US by that radio club.

I’m still procrastinating – but regretting it now – KCR had a matching transmitter, a low

power rig the same size as this receiver – but they discontinued it. That would have made

a nice looking small QRP station.

Arnie, your post reminds me to ask at our Post Office, if we can now mail things like bags

of FETs or variable capacitors and such, now that mail connections have been restored.

26062. Review on the "Isolated" Variac I bought (another long ramble)

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-02 19:24:35 UTC
From: Phil
Topic: 26062 Message: 26062

First, let me say that I wanted to purchase BOTH a variac & an isolation transformer. My workbench is relatively small, 48" wide and 24" deep, with a pegboard back for tools and an overhead shelf (with fluorescent lamp on the under side) that is ideal for holding test equipment. On that shelf left to right is a Heathkit LG-1 Sig Gen, Heath IM-21 AC VTVM, Heath V-7A VTVM, Heath IT-12 Sig Tracer, Leader LSG-17 Sig Gen and finally TWO metered "Tekpower TP-3005D" 0-30V 5 Amp regulated Power Supplies. Those Power Supplies are the latest addition to the bench and let me say, they are ABSOLUTELY WONDERFUL! Separate digital meters for Voltage/Current, they have adjustable current limiting. Cooling fan comes on when you put enough load on it to heat it up a bit. You can hear relays switching transformer 'taps' as you vary the output Voltage across it's range (that reduces the workload heat stress on the series pass transistors.

On a separate cart next to the bench is the B&K O'scope, 2.4GHz Frequency Counter, Volteq SFG2002 Function Generator (to take care of stuff below the range of the Heath & Leader Sig Gens). And finally a RadioShack 13.6V 19 Amp supply to work on larger radios.

So my bench is (Finally) pretty well equipped, the only thing that was really lacking was a tube tester (some day down the road) and a variac/Isolation transformer.
****

But this is REALLY about the Variac I bought, both the good and the bad!

I needed both a Variac and an Isolation Xformer, but like I said, don't have a big bench. I REALLY figured that a 500va unit would be MORE than large enough as I DON'T do tube transmitters and such now-a-days (can't man-handle them, not even a boatanchor like an R-390A etc

While shopping (for new, I don't do eBay) I ran across ONE unit that combined BOTH an isolation Xformer AND a Variac. It was called an "Isolation Variac", BUT at about 1000va it was larger and heavier than I really needed. But for convenience I decided to buy it anyway. Reviews indicated that it IS a TRUE ISOLATION transformer.

This is the unit I bought. . .
http://www.amazon.com/Variac-Variable-Transformer-Isolation-1000va/dp/B006NGC6HU?ie=UTF8&redirect=true&ref_=ya_st_dp_summary

I read the reviews, both good and bad and decided to buy it anyway, figuring if it DID have problems I could fix it or return it. ONE of the things that repeatedly came up in reviews was a "wobbly shaft and excessive knob height". I figured I could probably take care of that IF mine had those bad 'features'. It did. . .

****

When it arrived I was a bit surprised, the unit is larger and HEAVIER than I expected (about 21 lbs). And like others said, it "STUNK" with a capital S. That doesn't bother me, a lot of the Chinese stuff I've bought stunk when first opened but it dissipates fairly quickly.
****

Examination showed that YES, it did have a 'WOBBLY SHAFT'. After making SURE that the unit was fine electrically, no sparks, or bad/bouncing readings when adjusting the Voltage (in other words, good contact between wiper and transformer windings) I then checked to make SURE that it is truly an 'Isolated' variac. IT IS, there is NO continuity between the primary and secondary windings. ONLY the round ground pin from the AC line input is fed through to the outlet. I feel that is a GOOD thing as it's only a safety ground, but important.

I used my DVM to compare the actual Voltage output against that which the analog meter showed. I checked it at BOTH 50 & 110 Volts output. As close as I could read the small analog meter the readings were DEAD ON accurate. That was a surprise!

NOTE: Some reviewers have said that the Voltage output doesn't correspond to the knob reading. DUH!! First, the arrow on the knob doesn't line up with '0' when it's turned all the way down. SECONDARILY, actual Voltage output will depend on what you put into it. Some people have NO CLUE. . .
****

NOW TO SEE ABOUT FIXING THAT WOBBLE!
Having determined the unit is working correctly, no obvious electrical problems, I pulled the knob and examined the "Wiper assembly" to see why it wobbled (the shaft goes all the way through the unit and is visible from the bottom. Appears to have a lower bearing OK.

The "wiper" is on a husky piece of plastic (think it's white Nylon). There are two metal inserts on that plastic thingy, and two setscrews that are threaded into the metal inserts. NOT easy to get a screwdriver in to check their tightness.
****

HERE'S HOW I FIXED THE SHAFT WOBBLE. . .

1. I found that taking two screws out of the front panel that holds the meter, switch and outlet there is a nice large hole that allows access to the setscrews and upper shaft. I checked, one setscrew was loose, the other one not as tight to the shaft as it could have been.

2. I loosened the second screw, pushed DOWN on the wiper assembly and tightened the set screws. This alone took most of the wobble out of the shaft, still had a little bit as it doesn't have a true bearing at the top.

3. Examination showed that I could probably make it better though. I found a round piece of phenolic about 2.75 inches in diameter and 1/8 inch thick. I drilled a hole in the center and slid it down over the shaft. This was to act as a washer or "rubbing surface" for the knob (there are three screws in the top, under the knob that would otherwise rub).

4. I then drilled the knob shaft hole ALL the way through the knob. This allowed pushing the knob further down the shaft so that it was actually lightly rubbing on the phenolic washer. In this position the shaft protrudes out the top of the knob maybe 1/16th inch, perfectly tolerable!

5. Checked ALL my work, VOILA! Almost NO shaft wobble at all. Remounted the front meter panel with it's two screws. While it was off I checked the Chinese soldering, ALL soldering looked VERY good for Chinese workmanship!

6. I then checked to make SURE that there were no Voltage glitches or dropouts throughout the knob range, there weren't!
****

OK, if I were giving this a "star rating" (5 star scale), how would I rate it??????????????

As it came from the factory with the shaft wobble etc I would rate it a '3' as I feel that would probably affect long term reliability.

AS IT IS NOW AFTER THE MODS, IF THE FACTORY SHIPPED IT LIKE THIS I WOULD RATE IT A FULL '5 STARS'. . .

Richard – old mail – but – where did you put the audio level control?
I don’t have an RAL handy – but i think maybe at the ‘audio limiter’ control?

What size pot, and where in circuit did you place this.

I have 2 RAL in storage, which i will try to sell at a Pacific Northwest hamfest – big boxes have to go first, so i can keep some of the smaller boxes.

tnx

Again, old mail i’m going thru, maybe i have posted on this.

What you say about off-tuning a single tuned circuit regen on VLF-LF SHOULD decrease the received signal a lot, in fact, greatly.

But i recall long ago i used a single 6J5 triode regen and received, in Seattle USA on the west coast USA, NPM Hawaii on something

like 19 kHz. They DID have a lot of power, i recall the QSL i had from them said 500 kW. I think i also heard NBA Panama and NSS

east coast. I recall i talked to another Seattle fellow who was using a 3-transistor receiver, single tuned circuit, and he had a list

of international VLF stations he was able to receive.

How and why these simple receivers worked as well on VLF, i can’t explain; it’s now kind of a mystery to me.

Maybe it’s just because the sending stations had such high power.

I recall in Seattle using a Frequency Selective Voltmeter and tuning across the frequency of NLK (near Arlington, Washington state,

less than 120 km from Seattle) and the needle on the voltmeter indicator would jump way up. I think i also heard NLK teletype

transmission sound on some rural telephones.

I suppose you’re right about the need then for an RF amp stage at VLF-LF.

Some manufacturers’ engineers were aware of the challenge.

I have a Marconi 730 which for receiving UK station GBR, has a switch position to throw in a beat oscillator, which is only used for

receiving GBR.

To: regenrx@yahoogroups.com
Subject: [regenrx] Re: regen for 600 meter band

“Until now my conclusion is, if the frequency is too low, a regen receiver used for cw without selective preamp would be deaf. For am on LW it only would cut off the sidebands. In 2012 i tried to receive the SAQ on 17.2 kHz. The distance is not very far from here, but a single stage regen receiver didn't work at all. With a Q=1000 the bandwidth is as low as

17 Hz. I had to tune the autodyne frequency to 16700 Hz. Tuned to this frequency a regenerative circuit has no amplifacation on 17200, but the noise of the grid leak resistor is still there. Later i tried my luck with a dc-receiver. In the meantime the regen stage had been changed into a tuned q-multiplier, then mixing down to audio. The signal was loud and clear. This circuit is still working well, also the alphas can be heard. “

Good info, Phil !
I'll have to look into the highvoltage supply you use. I have a couple Fluke 407 and a Heathkit supply; they're all vac tube regulated so they're kind of large.
Also, do your signal generators actually tell you the microvolts output? I have a URM-25E which is a nice machine, but it weighs a lot (about 35 lbs.) and
i have read that it also can be hard to service (repair).

Hue, OM:
I replaced the 6D6 1'st audio grid resistor with a pot, 100 K, and connected the wiper to the grid. I put it in the hole for the "DC Power" switch, which is easily replace if one would want to. There is a hole in the chassis near-by to route shielded wires to the top. The grid resistor is mounted behind the panel in the top right quadrant.

There is no difference in performance with ac or dc on the heaters, but I use dc, "just because." Actually, on ac there is a wee bit of hum picked up by the inductors in the low-pass audio filter from the magnetic field from the heater wiring, which disappears when the filter is switched out. The instruction book notes this wee hum as an indication the receiver is working correctly...

Date: 2016-04-03 21:48:21 UTC
From: Phil
Topic: 26067 Message: 26067

Perhaps a year or so ago I built a very nice "DBT" (Dim Bulb Tester) in one of those classy little aluminum and fiber Cases that Harbor 'Fright' sells. Went the extra mile to make it nice, lamp socket in the lid, double duplex box with a power switch and outlet, 3 wire power cord and of course storage for a few light bulbs.

With the new isolated variac it's not likely it'll get much use, but it's way too nice to "part out", cost too much to make it worth the cost of selling it/shipping it, etc.

Guess I'll hang on to it either as a curiosity or for some "quick testing" of some questionable device.

Perhaps if I run across a neophyte BA enthusiast in the local area I'll pass it on to him. . .

26069. Completed construction of my Receiver Multicoupler today

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-04 03:51:22 UTC
From: Phil
Topic: 26069 Message: 26069

Hi All,
First you might ask what this has to do with regen receivers. Well, my regen is one of the receivers that will be connected to this critter :)

Sometime back I mentioned that I was building another multicoupler to allow multiple receivers to share the same antenna. Only this time I'm making a few changes and additions to it, most notably switchable BCB band rejection AND two LF to HF converters to allow receivers that don't normally tune the LF range, or don't do well down there to receive the LF range in the 4.0 to 4.5MHz range. Yes, I could have done the job with a single LF converter, but that would have complicated switching.

Here's the basic "specs" of the unit.
1. Frequency range is 10kHz to 30MHz (actually a bit more but that's the 3dB points of the splitter I used).

2. Switchable between two antenna inputs, one passive and one "active" to provide power to an active antenna such as as mini-whip.

3. 4 separate receiver outputs, each isolated from the others to prevent interaction. Two may have a switchable 4MHz LF converter switched in.

4. TWO switchable BCB reject filters (only one can be selected at a time). One is a 530KHz Low-Pass Filter, the other a 530-1600KHz band reject filter. That way I have the choice if I only want to listen below 530KHz, OR if I want to be able to listen to either LF & HF with no BCB IMD.

5. ALL RF switching, filter selection, LF Converter Selection, Antenna selection etc is accomplished via 12 Volt relays (7 of them). This GREATLY simplified wiring as it reduced the amount of open wires carrying RF, allows for greater isolation between inputs/outputs and so forth. All that's carried from the front panel switches is 12 Volts DC. The LPF on the main amplifier/splitter board is completely enclosed with grounded copper foil. I didn't go that far on the other modules, I ran out of foil.

6. Ideally a multicoupler should have little or no RF gain. As in the last coupler I built, I was shooting for about 0-6dB of gain, with a 50 Ohm 6dB pad between the amplifier output and the input to the splitter, primarily to insure a good impedance match. I haven't measured the exact gain on this one, but basic testing on a local beacon (FCH-344) shows that it's right in that range.

7. LF/HF Converter Gain. Basic tests with FCH-344 shows that there IS about a 10dB gain at 4.344MHz as compared to tuning it directly at

344kHz. That's using the Icom R-75 as the test receiver (the R-75 has had the LF attenuator bypassed).

8. The only controls are mini toggle switches for Main power, Active/passive antenna, BCB filter select (LPF/Off/Band Reject), RX1 LF converter, RX2 LF converter. EVERY switch has a different colored LED above it to indicate the status of the unit at a glance (love them LEDs).

9. The bench Power Supply metering showed that the unit draws about 180mA with everything switched on.

Tomorrow I plan to dig out my (new) Brother label maker and make labels for all the switches and connectors, put the top cover on the unit and then install it in the operating position. Then I can put it to the REAL test.

26070. Pictures of my latest creation, a 4 port Receiver Multi-coupler

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-04 20:04:17 UTC
From: Phil
Topic: 26070 Message: 26070

Hi All,
The other day I mentioned that I had basically completed building my latest 4 Port Multi-Coupler. Note, this device allows up to 4 receivers to share the same antenna wit no losses.

Today I labeled all the controls and buckled it up, installing it in the operating position. Just waiting for some 3 foot long BNC cables to arrive via UPS today to connect it all up.

Anyway, here is a link to the pictures I took (no Photobucket membership required to view). . .

http://s38.photobucket.com/user/ko6bb/library/KO6BB%204%20Port%20Receive%20Multi-Coupler-2016

Any and all comments & questions are welcomed. Schematics and information on the basic unit are in the home-brew section of my web site.

26071. Oscillator Circuits Receiver vs Transmitter

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-05 15:55:04 UTC
From: danyoder.cs@...
Topic: 26071 Message: 26071

Hi All,
Can someone explain to me the difference between lets say an Armstrong, or Colpitts oscillator circuit that is first being used in a regen, getting its source from the antenna and the LC filter, as apposed to a oscillator that is designed using a crystal or a tube and LC. Do they both have grid leak circuits and if so do they do the same thing?
Thanks Dan
W3DKY

26072. Re: [regenrx] Oscillator Circuits Receiver vs Transmitter

Yahoo group: regenrx (2016 — 2017)

From: Bill Cromwell
Topic: 26071 Message: 26072

Hi Dan,

Regen detectors are oscillators with controlled positive feed back so that it can be almost oscillating or oscillating. Probably any oscillator design will work but apparently two or three designs lend themselves more readily to the feedback control. All oscillators have positive feedback. Negative feedback kills oscillation and is used for neutalizing amplifiers that we don't want oscillating.

There are a lot of oscillator designs and they are the same whether they are in a transmitter or a receiver. And whether they are xtal controlled or LC controlled or RC controlled. Whether they are keyed fo CW or left running all the time. Same-same.

Do you have something in mind for a project?

73,

Bill KU8H

FOR SALE: H113/U Military Headset

New old stock. Perfect shape. This is a top quality Medium / High Z, 600 ohm head set by Audiosears.

Very nice, functional military memorabilia. New in original packaging and box. Unused. Well below eBay prices.

Available for $25.00 plus shipping

Thanks Bill,

I am just trying to sort out the differences in an oscillator circuit used for receiving and transmitting or even just calibrating.
Like the HRA-10-1
Does the grid leak circuit do the same in an Armstrong circuit for both receiving and transmitting circuits.
Thanks

Back again with a question
I used to know at least three or
four different oscillator circuits by
how a particular circuit was divided.
Say Armstrong had a divided Coil
Pierce divided Capacitors
Hartley again divided inductor.
Culpits ….. ???
Another … ???
And another ???
what were the other ones can someone
remind me I think I forgot, and don't
see my little booklet :)
If memory serves me correctly it was a
very easy to learn trick to make it easy
to tell the difference in half a dozen circuits.
At least the three or four main ones…
Thanks Everyone

From: William Wood
Topic: 26079 Message: 26079

I found that oscillator book we were talking
about a couple of days ago. It’s titled:
Oscillator Circuits and it is from the Sams
Photo Pack series ‘Basic Electronics Series'.
I paid a dollar or two at a swap fest so they
are around. Not sure it is worth $15 that is
being offered at ebay right now. It’s paperback
with 125 pages, my copy was in it’s 6th
printing and dated 1964.

If you only wanted a couple of pages I’d be
happy to xerox them for you and send VIA
an attachment. It does help you see what is
going on in those circuits. IF I ever run across
another copy or two el cheapo, I will glomb
onto them for folks interested.

I’ve included a link for an ebay copy of the
book and while I like the shipping cost, I think
he should come down a couple of bucks. :)
Only because I’m a cheap skate :)

So what ARE the copyright rules for a book like this... printed 52 years
ago?
Is this protected or can we scan and share circuits from this book?

I'm not sure of the copy right rules
I do know this is no longer being published
and if you are not copying the whole book,
only small sections, and for educational
purposes and such, they will not worry. I
got permissions from other publishers to
copy, as long as I did not sell, or claim I
wrote it.

We'll let the folks that know chime in, but
I'm not making a dime, nor am I claiming
I wrote it so I think we are good in that
department.

Sams I think sold and gave away most
of their material years ago, and I gave away
two 4 drawer filling cabnets full of those photo
fact envelopes. And they are all available on
disks now I believe.

Let us know what you guys think

Bill wrote:

> All oscillators have positive feedback.

Not so. Some oscillators work by generating negative resistance by means other than positive feedback. (When a tuned circuit is connected to a negative resistance of a high enough absolute value to overcome losses in the tuned circuit, the result is oscillation.) The dynatron is such an oscillator; so is the transitron. Wikipedia has good coverage of both.

A transitron oscillator is straightforward to build at shortwave frequencies with any RF pentode that has a separate suppressor-grid connection. I've done so and then attempted to use it for detection in the manner of positive-feedback regenerative detector. But the snag with oscillators that don't operate by means of positive feedback is that their output is low, as they don't exhibit the high gain we take for granted with positive feedback (regenerative) circuits. So my experimental transitron detector was barely able to detect anything, even a very strong test signal on the bench.

Topic: 26089 Message: 26089

Hi,

I built a prototype using resonators from Rob (Thanks again) and it works well at night when there is propagation. However the tuning range is 7014 to 7094. I would like this to be either wider or higher in frequency. Does anyone know a solution other than changing the variable capacitor (Mine is 16-116 pF).

I did not ground the resonator.

Resistance is a property of materials, and negative resistance--actually negative _differential_ resistance--is a property of some materials and some systems under particular conditions. Positive feedback happens to be a particular means--a special case--of obtaining negative resistance. All electronic oscillators oscillate by means of means of negative resistance, but positive feedback is only one among multiple means of producing the negative resistance necessary for electronic oscillation.

Wikipedia's coverage of negative resistance is very good, and I highly recommend it as a read for regenerative-receiver folk. (Negative resistance - Wikipedia, the free encyclopedia https://en.wikipedia.org/wiki/Negative_resistance

https://en.wikipedia.org/wiki/Negative_resistance

Negative resistance - Wikipedia, the free encycl...
https://en.wikipedia.org/wiki/Negative_resistance In electronics, negative resistance (NR) is a property of some electrical circuits and devices in which an increase in voltage across the device's terminals res...

View on en.wikipedia.org https://en.wikipedia.org/wiki/Negative_resistance
Preview by Yahoo

) Just ignore the math--I do--and concentrate on the narrative text. As the coverage proceeds you will encounter our beloved regenerative detector, as well as the Poulsen arc transmitter, the dynatron, Gunn and tunnel diodes, and more. All of these involve negative resistance, but only the regenerative detector (among the negative resistance generators I just mentioned) involves positive feedback.

We can also build oscillators--at least at audio and lower frequencies--with gas-discharge tubes like neon bulbs and voltage regulator (VR) tubes. These devices also exhibit negative resistance, and their negative-resistance characteristics also _do not_ come from positive feedback.

We regenerative receiver enthusiasts are direct benefactors of negative resistance obtained by means of positive feedback. The tuned circuit in a regenerative detector's positive feedback loop ensures that sufficient negative resistance (and gain) for oscillation occur only at one frequency. But a regenerative-detector flaw that especially users of triodes (vacuum tubes, JFETs, BJTs) may encounter, however, is _fringe howl_--a tendency of a regenerative detector to oscillate _at audio_ in the region at and just above the feedback level at which RF oscillation starts--at and just above _critical regeneration_. Fringe howl happens when an RF oscillator that uses positive feedback to generate its negative resistance oscillator seeks, but keeps not achieving, amplitude

stability at an AF or VLF/LF rate. When this is happening, the feedback loop produces _specific_ negative resistance at the tuned-circuit resonance, and _the entire oscillator/detector circuit as a one-port black box_ exhibits _generic_ negative resistance capable of leveraging RC time constants and/or LC resonances associated with the circuit's active device for oscillation at AF or VLF/LF. A self-quenching superregenerative detector--a type of _blocking oscillator_--leverages this effect on purpose. A superregen cannot oscillate at VLF/LF if it is not also oscillating at RF. _Squegging_ is a time-honored term for unwanted VLF/LF oscillation in an oscillator otherwise intended to oscillate only at RF.

Recently a RadioBoard contributor showed how using separate, adjustable negative bias on the gate of a JFET regenerative detector can serve to entirely suppress fringe howl. This is a technique I must try, as high tendency for fringe howl in JFET and BJT oscillators is a chief reason why I haven't much played with simple solid-state regenerative detectors. See how some of those classic JFET regen circuits have COARSE and FINE regeneratiion controls? Incorrigible fringe howl is the reason why.

26094. That good old-time AC-DC project

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-10 23:04:25 UTC
From: Hubert Miller
Topic: 26094 Message: 26094

Was just looking at a radio projects book, "Radio for the Millions", 1943, given to me free, at yesterday's NWVRS antique radio swapmeet.

I had looked at those projects before, but somehow it never struck me this strongly: all those AC-DC projects, with metal chassis and front

panel, directly wired to the AC input, not thru some isolating capacitor, as in home AC-DC radios, which would limit the shock current.

So when you plug the project radio in, you have a 50% chance that the front panel is directly connected to 120 AC. In vain did i look for

any word of caution about this in the book. Okay for us who have some experience, but the book talks about the complete beginner

buying parts from a list and assembling per the diagram.

I spent a lot of fun time as a youngster playing with unreasonably high voltages, but i think all those experiments were with high enough

voltage that it would throw you clear. A bare metal front panel and headphones both running right to the AC mains scares me.

I gave away maybe 30 lbs. of radio magazines at the same swapmeet, and came back with an SW-3 with 7 sets of plug-in coils i bought.

Hue, I think the 1943 radio builder didn't have to work on wet concrete floors like we do today. Also, there were two types of radio builders. There were those of us who knew not to grab a wire without checking for voltage first. The others are no longer with us.

BTW, Radio for the Millions was my bible for many years. I still have my original copy.

Leonard

Thank you Dave,

I was told/taught wrong by a teacher years ago. My view has served well
for a long time (around about 1960) but now it's time to adjust the view.

73,

Bill KU8H

Hi Leonard,

My father taught me all the safety lessons and those have been refreshed numerous times over the years. I was allowed to have the AC mains and high voltage power supplies to run tubes in my early teens - unsupervised. I'm afraid a younger generation doesn't have that kind of advantage. Probably very few of them will ever need to know any of that anyway.

If my concrete floor was wet I fixed that before I messed around with a hobby. Priorities ya know.

There are a couple at ebay for an exorbitant
amount too :) Don’t know why, but some folks
think if a book is out of print, all of a sudden
the pages are golden edged…
Theres a book on limited space antennas out
there too, that has been out of print for a few
years, and you can get it for over a hundred
dollars, or wait for the next swap meet and
pick it out of a misc box for a dollar or two.
fun subject…

Is it a design requirement that the chassis has to be connected to the power line? I have a Knight Kit AA5 radio from the 70s that used an isolated common bus wiring scheme, to which one side of the AC line was connected so The chassis was not directly connected to the AC line. Instead, it has a .05 uF capacitor from the chassis to the isolated common bus so the variable capacitor frame was at RF ground. As far as I can tell, it has no chassis shock hazard. And of course, it is in a plastic cabinet. I'm sure most of you regular fellows know all the problems and modern solutions for those 1943 designs. IMHO they could be built as long as you similarly modified the design like the Knight kit to avoid the direct chassis connection situation, Used a polarized plug, and an isolation transformer for testing then put it in an insulated box. An inexperienced Builder might not be able to make similar changes on his own, though. Or, best of all just use an isolation transformer for the power supply. Regards Mark. KB9VKE. -----Original Message----- From: 'Leonard Meek' lemeek@... [regenrx] To: regenrx Sent: Sun, Apr 10, 2016 06:20 PM Subject: Re: [regenrx] That good old-time AC-DC project

Hue, I think the 1943 radio builder didn't have to work on wet concrete floors like we do today. Also, there were two types of radio builders. There were those of us who knew not to grab a wire without checking for voltage first. The others are no longer with us. BTW, Radio for the Millions was my bible for many years. I still have my original copy. Leonard

Subject: [regenrx] That good old-time AC-DC project

Was just looking at a radio projects book, ☐Radio for the Millions☐, 1943, given to me free, at yesterday☐s NWVRS antique radio swapmeet.

I had looked at those projects before, but somehow it never struck me this strongly: all those AC-DC projects, with metal chassis and front

panel, directly wired to the AC input, not thru some isolating capacitor, as in home AC-DC radios, which would limit the shock current.

So when you plug the project radio in, you have a 50% chance that the front panel is directly connected to 120 AC. In vain did i look for

any word of caution about this in the book. Okay for us who have some experience, but the book talks about the complete beginner

buying parts from a list and assembling per the diagram.

I spent a lot of fun time as a youngster playing with unreasonably high voltages, but i think all those experiments were with high enough

voltage that it would throw you clear. A bare metal front panel and headphones both running right to the AC mains scares me.

I gave away maybe 30 lbs. of radio magazines at the same swapmeet, and came back with an SW-3 with 7 sets of plug-in coils i bought.

-Hue Miller

Hi Mark,

That cap from the chassis to the floating ground is subject leakage or a dead short. If it is the original you shouldn't trust it with your life. As you mentioned, the case is plastic and ther knobs probably are too. So there is no exposed metal part.

These radios are called AC/DC because they will run from the 120 volt AC line *_OR_* from 120 volts DC. So such a radio could be operated from a battery supply - perhaps with a multivibrator type of "inverter" to give 120 volts DC output from 12 volts DC input.

I have been running 6-tube receivers from batteries and I find it is very practical. I use a series stack of 9-volt batteries for B+ and those last several weeks in moderate use. They won't run the heater string though. For that you might get along well with one those newfangled DC-DC converters that can supply 120 volts DC from a 12 volt SLAB to the heater string in the AA5 and the series stack for B+. 90 volts (or even 45) volts of B+ may surprise you how well it will work.

73,

Bill KU8H

Hi All,
I believe I've mentioned my long time Radio Buddy, W6LRG ("Lazy Retired Guy", he's the one in his 80's I frequently help out).

For years he was an author for one of the local newspapers, the Merced County Times (it's free at many locations).

But he's also written some ham radio stories etc, and I believe also had some things published in ER Magazine (Electric Radio).

Today I ran across the CD that he gave me containing his article "18 Ham Radio Stories". It's also got some pictures of him and other things and I thought some of you might be interested. It's all in a zip file on my "Box" site.

NOTE: You DON'T need a Box membership to download, though I believe some folks have had problems in the past. . .

Here's the link to it.

26108. Radio for the Millions PDF IF 60MB is too big to download

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-12 15:54:19 UTC
From: Rob
Topic: 26094 Message: 26108

I have downloaded an entire library of PDF books.
It seems like there are ways to make a PDF that is smaller.
I noticed that the Radio for the Millions PDF is 60MB.
But some of my downloaded PDF books... same number of pages and lots of
hand drawn circuits
are only 15 MB.
So I would like to figure out how to convert the fat PDFs into much
smaller PDFs... and then perhaps
downloads would be 10 times quicker to share.

If anyone has a problem downloading the 60 MB Radio For The Millions
book I would share it on a DVD since they only cost a quarter.

Some day I may actually digitize my paper copy of this book if I figure
out how to make it any smaller than 60 MB.

That books is made up of pictures of the pages, that is why it's so bulky.

Might be the same number of pages but there is more white space in one than in the other (color pictures require a great deal of space). Realize that someone has already looked at this and optimized it all before you even thought about it. Black text and line drawings require the least amount of space since a pdf is a bunch of vectors generated and decoded by postscript. Alvin P. Schmitt

Topic: 26094 Message: 26111

Well guys..... that was interesting.
On LINUX MINT PC I opened the 61 MB PDF to read it and then printed it.
PRINT has the option to output as a file so I chose PDF and then the new
PDF output file
was created, no resolutions defined by me, it just was created in 20
seconds... as a 34MB PDF.
Which is just fine to read the text and the circuits.

So don't be so quick to declare WHY its so bulky or that someone has
already looked at this and optimized it all before you even thought
about it.
BECAUSE
I'm just getting started on how to reduce these fat PDFs even more.

Anytime I open a PDF file using a PAINT type program .....like GIMP ....
it asks to specify paper size ... in pixels or inches and resolution.
Playing with those numbers can tweak the resulting image size to much
much bigger or smaller final image saved size.... and that JPG can be
experted to PDF... where there are more options to choose output file
sizing.

So without playing with all those tweakage options... I already cut the
file size in half just by printing it to PDF.

And just out of curiosity I opened the 34MB PDF in the PDF reader and
told that to print again to output PDF file...
which produced another 34MB PDF. So its not like every PDF output
print would go smaller. It defined a specific size
resolution and printed it without giving me any options.

leonardmeek <lemeek@...>

26113. Mk.28

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-13 00:03:14 UTC
From: Leonard Meek
Topic: 21560 Message: 26113

I just uploaded the latest schemo of my improved Mk.28 Supergenodyne. Some changes are actual wiring changes, others are drawing error corrections. Again, I found the 12AU7 gave better results than the 6DJ8 for the LO. The 6DJ8 is better in the 2nd RF stage. The audio and PS are on a separate chassis. The AGC works better (no hicups) but is still overloaded on local stations. Time to move on.

Leonard

Hola amigos !
Nice to see the list alive...
will appreciate ver much if Leonard can send the
schematic of the MK28 Superregenerodyne to
my GMAIL address, as it is a lot easier for me to
pick the files there than to try to access the YAHOO
list from my slow connection...
The 12AU7 is an excellent tube, still in production
in Russia... It is, according to my analysis of the
tube's parameters, just to 6C4 classic triodes
packed into the same glass envelope !!! Right ???

26116. Etching Aluminum question

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-13 01:37:21 UTC
From: William Wood
Topic: 26116 Message: 26116

Hey Greetings Everyone
I bought a used cake pan and nice cookie sheet today,
and while I was waiting in the car for my wife to do her
shopping, I took some steel wool and started cleaning these
guys up. Pretty cruddy looking for being sold at good will.
Anyway, after about 45 minutes of cleaning these guys up,
I decided to get some etchant to give them a nice satin finish.
When I got home, I painted the inside of the cake pan with
the etchant and played with the thing for about 45 more minutes.
After rincing and cleaning it up it looked OK, but not the nice soft
satin i was hoping for. Perhaps the cold temp??? 50 degrees
would slow the etching process down a bit, so will wait for a nice
warmer day to try it again. Thought I'd ask you gurus if there was
a secret to getting the satin finish that will also cover up the small
scratches the steel wool did not clean up. I started cleaning these
up with a medium grade, and finished up with a brand x I think
almost ought 4 grade of wool, and if the inside does not look better
next time around, I am going to stick with the polished with steel
wool on the outside. It looks better then the etching does…
OK, any ideas??? Would like this to look like a million dollars.
I bought them because they looked good together, I did not have
a project in mind for them as of yet. The acid I bought was Muratic
and I used it full strength, as I had planned on sitting there until
the job was done…
Thanks for any feedback and critiquing and
73 fer now
Bill KE9XQ

Silk finish on aluminum chassis in vintage QSTs and ARRL Handbooks was done by bathing metal in lye-and-water mix, rinsing, and then buffing off residue. Find an old Handbook that describes that technique and follow it. Practice on scrap piece(s) first.

Yes, 12AU7 is 2x 6C4. Think total max plate dissipation is derated somewhat due to close proximity of the two sections.

To clean and etch aluminum you don't want acid, you want alkali. A lye solution will clean and leave a nice matt finish.

From: Jim Wiley
Topic: 26116 Message: 26123

One more thing: Try to avoid the steel wool, and instead use fine to very fine grades of wet and dry sandpaper. The steel wool will will "stick" in the surface scratches of the aluminum, and even if you can't see them, the remaining steel wool "fibers" will eventually become oxidized (rusty) and ruin the appearance of the work. Learned this a few years back when attempting to clean up a project box.

The reaction between aluminum and lye, or sodium hydroxide, produces sodium aluminate, which is the white-ish or grey-ish deposit you'll see forming on your aluminum. Just wipe or rinse it off.

The gas that is given off is hydrogen, so do not do this in an enclosed area and do not do it near an open flame or any source of flame or spark. Hydrogen if flammable and explosive.

Otherwise this technique is a good one for producing a nice satin finish on aluminum. It won't get rid of really deep gouges or scratches though. Those you have to remove with some elbow grease first.

Good luck.

See if you can find "Functional Circuits and Oscillators," by Herbert J. Reich. All of them are there. Anything that provides positive feedback will oscillate if there is sufficient loop gain. Look up the topic of "negative resistance."

Spoiler alert -- H. J. Reich was one of my professors.

From: William Wood
Topic: 26127 Message: 26127

Hey Guys
This latest oscillator book gave me
an idea. Some of you have been around
the block a few times, and others maybe
haven't gotten to the corner yet. So, I have
no book in mind, mind you, what if we chose
a book and go through it a chapter per week,
discuss, debate add to and learn a subject
inside and out. Like that oscillator book,
or if you could find one focusing on regens
there would be little or no off topic discussions
then. It would help if the book were readily
available to all interested parties, and those
of you that know the subject well, can kibbutz
or add to the knowledge base as you saw fit.
That way there is something for everyone.
A little learning/tutoring and when we are done,
we might know what we are talking about.
No plans yet, just debate the idea and give
us a dozen books worth our efforts…
What Say Ye?
73 fer now
Bill KE9XQ
PS if a chapter per week is too fast for some,
we could do two weeks, or as long as the
discussion lasts… juss thinkin

I bought the 1964 OSCILLATOR CIRCUITS Adams book because it was
described as
understandable for newbies and because it was 125 pages written without
expecting me to
have a PHD in math and electronics.

I have a library of tube and radio books that are 400 pages of theory
with calculations
made up of symbols I can't even make appear in an email text.
So I figured this would be a good resource to examine.... and share.

I will scan it to share it online and then anyone can comment without
guessing how to chase down a page.

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } That would be interesting, I would check in for that.

The "dc" capability was for more than just battery supply. Some pretty large sections of major cities had 120 V _dc_ mains (a side-effect of dc supply for streetcars/subways), even until relatively recently. In New York City, for instance, Consolidated Edison switched its last dc customer over to ac in _2007_ per this press release:

Con Edison: newsroom - news release - A/C But No D/C: Last Con Edison Direct Current Customer is History http://www.coned.com/newsroom/news/pr20071115.asp

And BTW that wasn't necessarily very clean dc. I recall here and that that the dc supplied commonly had more than a little commutator ripple on the feed.

Hard for me to believe that actual residences were supplied with DC, altho i suppose it was possible. That would make life near impossible, wouldn't it, for home appliances?
I cannot think of a single 115 DC refrigerator on the market. Think about rechargeable appliances and TVs.

Somewhere i read about an incident in NYC where someone plugged in an AC radio to their DC supply, with predictable results. I wish i could remember where i saw that article and how long ago this incident was supposed to have happened.

I have a Philco Tropic radio with multiple SW bands, that was, i was told, made for 240 volts DC in Europe. I don't know how accurate that is; i suppose i'll need to find the original schematic to verify that. It DOES use a couple battery tubes in the output ONLY - type 49 - and because of this, there's a pretty good AC hum always - due to AC on the tube filaments now. I looked at tube manuals for quite a while, trying to choose a sub for the 49 tetrode, but i think eventually i'll just put in a small DC supply for these 2 tubes' filaments.

Hi Hue,

Yes 240 DC was used in Europe. I was around Southhampton, (UK) in late 60's and they were slowy changing over.

TV's and Mains powered radios worked with little problem. Troubles arose when TV's went to solid state diodes, one for HT and another in reverse direction for filement supply, saved on dropper resistors and improved the current balance of AC current.. Of course working on chassis at -240 was not comfortable. As was working on chassis connected to 240 AC the wrong way round.

Every thing transformerless of course, anyway transformers cost money!!

Cheers
Will

Here are two BJT regenerative receivers in which the base-collector junctions have been reverse-biased to avoid these above-mentioned problems.

Yes, and a look at the "Type of current" column in the "all countries" listing at http://www.trade.gov/mas/ian/ecw/all.html http://www.trade.gov/mas/ian/ecw/all.html is eye-opening, as some countries remain on dc feed.

I Use a Firefox add-on called "Down Them All" all the time. It will
allow you to download ALL the files of a specified type at once. You ca
specify the type as "Documents", Images and so forth, or a specific type
such as .jpg. I collect Old Time Radio shows, usually in mp3 or zip
format and have downloaded literally thousands of files with D-T-A.

I have still to test the uppermost schematic with the improved emitter follower regen. The lowermost receiver performs well. Because of the lower internal basis-collector junction capacitances by reverse-biasing these junctions the tuning range has been improved at the Medium Wave Broadcast band. The small base coupling capacitor of 20 to 40 pF ensures that the tank circuit is lightly loaded. And the benefits of separating the detector and Q-Multiplier stages is that the sensitivity is improved, because each stage has been optimized for its purpose and squegging/motorboating is avoided by the small RC time constants in the Q-Multiplier sage.

You are all very welcome.
The response has been from many.
My goal here was to blow it up big enough to be able to read it on ANY
device, even an IPHONE,
without anything special loading like PDF or KINDLE viewer.
And when I say blow it up I mean really magnify it.
My vision is impaired and I can't read the paper book so it will go in
the mail and land on Dan's doorstep.

For those of you wanting to pull ALL images at once down to a PC.....
check back again and there will be a ZIP file at the bottom of the page.

Don’t know if you have this or not,
so just one more book for today…

While I’m here, anyone interested
in the old NRI radio course???
I bought it off ebay a year or so ago.
Be happy to send it if there is an interest.

26155. RE: RE: [regenrx] That good old-time AC-DC project

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-15 01:46:02 UTC
From: Hubert Miller
Topic: 26094 Message: 26155

I don’t think this list is well maintained; in fact i think it’s history. DC is gone. WIkipedia shows Arentina as 50 Hz AC and British VI is 110v 60 Hz.

One thing i have long thought strange is Japan’s system, with part of the country 50 Hz and part 60 Hz. That wouldn’t seem to make good sense,

but good sense isn’t always in good suppy. Maybe this makes it more difficult for foreigners to export electrical equipment to Japan, and thus is

protective.

My friend Brad travels overseas to teach use of the machines his company manufactures. If i recall, i think he told me about seeing in Saudi two

different AC mains sockets in the same building.

Yes, and a look at the "Type of current" column in the "all countries" listing at http://www.trade.gov/mas/ian/ecw/all.html is eye-opening, as some countries remain on dc feed.

Best regards,

Dave

Yes! Twenty years ago I was in Saudi Arabia, half the country was 50 cycle, and half 60 cycle. In one house I found a wall outlet with one socket wired for 127 volts and the other wired for 220 volts, both unmarked. They bring 220 volts three phase into houses so you have 127 volts to neutral. You have to buy lamps rated for 130 volts or they don't last long. They bought equipment from every country in the world, made to different national standards, and it was a challenge to make it all play together.

Greetings Folks
At the risk of our moderator’s patience growing thin,
I will send only two more files for the near foreseeable
future. This one and one more shortly to come to past.
The context of these files will teach us all the regeneration
parts of those radios :) So, not totally off topic :)
Hope it is worth your time otherwise sorry for all the spam.
This was sent by request too, so:
Thanks for everyone’s patience, and

Brilliant stuff, Bill !

In them there days, many authors had a mastery
of language and the ability to impart understanding
of basic principlesthat Multitube etc just don't match.
And many of the illustrations were clearer, too.

When you feel brave again, moderator volentis, send us more!

26162. Re: [regenrx] That good old-time AC-DC project

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-16 02:42:06 UTC
From: Sam Neal
Topic: 26094 Message: 26162

Hello,

Just some useless information - Houston Lighting and Power Company shut down their last DC generator in 1979 and removed all of the very large copper " wires " to prevent theft. At the time they shut down the DC gererator(s) they had 11 DC customers, all old style elevators in the older downtown buildings.

73,

Sam Neal N5AF

The "dc" capability was for more than just battery supply. Some pretty large sections of major cities had 120 V _dc_ mains (a side-effect of dc supply for streetcars/subways), even until relatively recently. In New York City, for instance, Consolidated Edison switched its last dc customer over to ac in _2007_ per this press release:

Yes indeed,

240V DC was used in UK as well as in Europe. As a lad my father told me about having i in school in the 19430s - 1940s.

It seems they wired up a hand rail in one of the classroom sand the teacher had great dificulty letting go. But that was legend, I don't think anyone was injured, died or permanently harmed.

DC mains power was also used in Australia. In Sydney, dynamotors were provided in at Town Hall and Lang Park to supply direct current to customers. Alternating current was adopted as the new standard from 1930, although the first AC substation did not come into use until 1935. The AC system was not completed until c. 1958. No new DC customers were accepted after 1935, but the existing supply continued, albeit with mercury-arc rectifiers in later years, until 1985.

26165. Oscillator Discussions OR Regen Discussions???

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-16 18:49:23 UTC
From: William Wood
Topic: 26165 Message: 26165

Greetings Folks
I did not see a book yet that would be a good one
to focus on as the oscillator book was. But have to
admit that I have not looked very hard either :) Do
you know of a good book to tackle?
Was just wondering if those that had a chance
wanted to tackle one chapter at a time and discuss
the ins and outs, maybe share a schematic or two
and debate the qualities or shortcomings of a particular
circuit? I think the book that we have and or shared,
is a great little book, or we can do a different one.
I only saw two or three people that gave me the idea
they would not mind running with the thought. If there
is not enough interest, we can just do it ourselves, and
ask the gurus on board for further info if need be. Only
thinking of this as a time framed goal that would make
us do the study, as to my habit of letting it sit on the
shelf and only looking for it if I had a question :)
Only asking if there is actual interest, and which way
those interested would like to go with it. ???

26166. Reminiscing, my 8th Grade Science Fair Project

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-16 20:12:57 UTC
From: Phil
Topic: 26166 Message: 26166

Hi All,
WAY-WAY back when I was just a young sprout, I wasn't sure what I wanted to enter in the "Science Fair" (don't remember if that was the 'official' name or not).

Well, just about everybody knew that I really had only one interest in life (and they weren't girls at that time ;-) In fact, I had trouble keeping interested in most of the classes, though I managed to keep from bringing home any D's or F's (I'd have had a 'Parental Conference' if I had).

The science teacher suggested that I bring something "radio" and demonstrate/explain how it worked.

One of the things I thought of was taking my Signal Generator (think it was an Eico), a small AA5 receiver, mic and pre-amp and use it all as a mini broadcaster. But that was a lot to lug to school on a bicycle, and I didn't think it would be a good demo.

Then I looked at a box of parts that I'd scrounged from some junked out radios, mostly AA5's. When I parted out something (and I had a good source in the local TV/Radio shops), I saved EVERYTHING usable, including old resistors, capacitors, tube sockets etc.

Eureka!! I'll build an AA5 (All American 5) receiver. Only problem, funds were about non-existent, as was a suitable chassis (the one thing I didn't keep from parted out sets were the chassis and cabinet (if it had one). Besides, it would be hard to make a suitable display that way, it might look like I'd just pulled a radio out of it's cabinet and not put any effort into it.

Then an old magazine article extolling the virtues of "breadboarding" projects lit up a lightbulb in my head. I needed a breadboard, and I knew just where to find one.

Doing a couple uncalled for chores around the house followed by sweet-talking mom and I was the proud owner of one of her kitchen breadboards (think she was happy to be able to buy a new one anyway ;-) It wasn't pretty, but it was functional.

Taking my prize to the garage (which was my bedroom & shop) I gathered up all the needed parts, tube sockets, tubes, IF cans, output Xformer, tuning cap, speaker and so forth.

I think the only thing I bought was a Ferrite 'loopstick' for the antenna. Anybody here remember those? They were a small adjustable antenna coil with a short wire on it to act as the antenna. They were

often touted as a universal replacement for damaged loop antennas. The board was too small for the large loop antennas that typically resided in the back of old sets.

After the donkey work was completed the real job began, laying out the entire collection of 'scrounged junque' in the order of signal flow. I don't recall how long it took to assemble all of it, probably about a week as I was a very experienced builder by then. . .

The first time I plugged it in I stood back as I wasn't really sure what that Frankenstein Monster would do when hit with 110VAC!

SURPRISE, it worked! Only problem is, with no natural chassis shielding etc it also oscillated to beat the band. Whistles and squawks like you wouldn't believe. But with some careful tweaking and rerouting of some wires I got it tamed down and it actually played music.

I then made up little paper labels briefly naming each stage, then borrowed mom's typewriter and made up a "poop sheet" describing what each stage did.

A couple days or so before the science fair the teacher asked me how it was coming. I described it to her and she asked to see it. When she saw it she was HORRIFIED that I intended to plug that thing in and display it!!! Said if I wanted to enter it AND power it up I had to put a safety cover over it (this fits in with a recent discussion we had here on AC/DC power)!

To this day I have NO idea where dad got it, but he pulled a magic act and brought me a piece of clear plexiglass (or whatever the clear plastic of that time was) cut to the proper size to fit over it. A couple pieces of wood to cover the front and ends held the cover in place.

I think that was the ONLY time I ever got an "A+" on ANYTHING in school, lol.

A high coupling capacitor between a tank circuit and a regenerative detector can also introduce squegging/motorboating due to the large RC time constant with the coupling capacitor and the base bias resistor network. Best practice is keeping this coupling capacitor between tank circuit and base of the regenerative stage low and connect a separate detector onto the tank circuit. BJT detector onto a low-Z tap or a link coil.

I am looking for these B&W plugin coils: 20 MEL, 10 MEL

I bought what looks like the “Novice Pair” from the “How To Become” ARRL booklet of the late 1950s.
I wasn’t up to the metalwork, hi.

(Seems to me the more basic 3V4 receiver and slat-board transmitter of the 1953 edition was a lot more do-able

for young people.)

Now re the ARRL's 'Novice pair receiver' in the late 1950s ARRL booklet "How To Become a Radio Amateur",

i note:

The tube choice, 2x 6AQ5, seems kind of odd to me. I'd think the detector would more likely be a 6AU6 or 6BA6,

rather than a power tube. And the output tube wouldn't really need to be that large either, something like a

6AK6 would be fine.

There is NO volume or gain control, only regen control. Not so good.

The coils are low-inductance for the bands chosen - that is, the tuned circuit, for stability, is intended to be high-C.

Even so, the text says the receiver will probably not be useful above 40 meters (7 MHz) band. (They mean not

useful, for CW reception, because of stability, on the upper Novice band of 21 MHz.) The top coil tho, does tune up

to something like 30 MHz.

Do read the original QST article, wherein the author discusses why he used 6AQ5s. Tubes of the classes you're describing were evaluated. Every additional complication would have lost more readers and more potential builders, including the addition of an AF GAIN control. The target audience was high-school kids on tight budgets. On the other hand, prefab coils--B&W transmitting coils--were used because doing so end-ran the entire "I can't wind the coils" problem.

> The coils are low-inductance for the bands chosen – that is, the tuned circuit, for stability,
> is intended to be high-C. Even so, the text says the receiver will probably not be useful above
> 40 meters (7 MHz) band. (They mean not useful, for CW reception, because of stability,
> on the upper Novice band of 21 MHz.) The top coil tho, does tune up to something like 30 MHz.

Yes, the receiver would not have been very stable at 21 MHz. (As the "Novice Special"--which is what its author, Don Mix, W1TS, called it--was intended for, er Novices, how it might have behaved at frequencies other than 3.5, 7, and 21 MHz was secondary.) And, as he acknowledged, its performance at 15 meters would have been poor. But so would have been the performance of the cheap superhets that Novices were buying that covered that relatively new ham band. (In fact, _most_ two-dial general-coverage receivers, even those of medium to good pedigree, right up until the era of two-dial superhets ended, are and were pretty poor performers up there.) Which is why, instead of wasting time and effort trying to make the set work well at 15 meters--it could not have--in a subsequent issue of QST he described a 6AN8-based band-imaging converter that used a 17.7-MHz crystal to bring 20-, 15-, and 10-meter signals to ranges between 3300 and 3700 kHz and 10 to 11 MHz.

Mix explained his chose of 17.7 MHz as follows: "An oscillator frequency of 17,700 kc. was chosen for two reasons. First, it puts the center frequencies of both bands [20 and 15 meters] at the same point on the receiver dial, making it unnecessary to shift the band-set capacitor when changing bands. Second, the low-frequency limit of the regenerative receiver's tuning range with the 80-meter coil is about 3200 kc. Other oscillator frequencies would move one band or another closer to or beyond this limit."

A few more aspects are worth noting. For one thing, adding a crystal-control converter head of the receiver makes it a Regenerodyne. Second, Mix notes that sometimes the 6AN8 pentode

mixer can be made to oscillate at particular input-tuned-circuit tunings when no antenna is connected. As I describe in my page at http://dpnwritings.nfshost.com/ej/hybrid_mixer/ http://dpnwritings.nfshost.com/ej/hybrid_mixer/ , we now know that the reason this happens is that feeding the crystal-oscillator signal to the 6AN8 mixer cathode in the manner described by Mix makes the mixer regenerative by means of Colpitts-capacitive-divider action.

Finally, in this forum in the past considerable hand-wringing has been devoted to the somewhat over-the-top mechanical construction (and the templates for same) of the Novice Special and its related converter. I agree that the construction method used was overkill then and now, but I think also that we can excuse Mix for this elaboration for two reasons: (1) Staff-constructed articles in QST were as much about window dressing and doing a classy job as getting something that merely worked. It wouldn't have done for the ARRL Lab to turn out hammy junk built into cookie tins, and we know the set went on to be included in _How to Become a Radio Amateur_. (2) The tendency to provide over-elaborate instructions and templates came naturally to Mix by this time, as he was single-handedly manning ARRL HQ's Technical Information Service, which among many other things had to support readers' efforts to build and succeed with circuits, especially staff-produced circuits, published in QST, the ARRL Handbook, and other League publications. So it is that we can see Mix provide a similar over-the-top, templates-and-all treatment to the 6C4-5763 Boosted Pierce "Novice" transmitter he published in October 1968.

Best regards,

Dave

OK, I guess three is a good even number :) I know if we
start something others will chime in. They would have had
we not named and focused too, and we'll be happy about that :)

While we are waiting for someone that could teach the subject,
if no one says they would do it I would be willing to coordinate.
If everyone wants to do so, let's read the first chapter this week
and start our discussion Next Saturday. And, if all goes well, we
can discuss chapter one the following week unless you have a
point of interest you'd like to bring up right away. Then each week,
we read ahead the next chapter, while we are talking about the
chapter we have read before.

What I am thinking here is that you have a whole week to learn,
study or compare before we start the discussion, and then while
we are talking about that chapter you are starting to prepare for
the following week. During that week of contemplating the subject
at hand, if you can find similar schematics or ideas from the Internet
archives,you can share at your leasure.

If anyone does not have that Oscillator book we can make sure you
have a copy. There are only ten chapters in this book, if you'd like
to continue the subject, we can do the bigger book just shared right
after the smaller book. This will bring to mind much of what we'd
just talked about but it could help make things sink in a little better.
Only if the interest survives :) The Bigger book goes into a LOT
more detail :)

73 fer now Folks

On Sunday, April 17, 2016, 16:21, Hubert Miller kargo_cult@... [regenrx] <regenrx@yahoogroups.com> wrote:

Now re the ARRL's 'Novice pair receiver' in the late 1950s ARRL booklet "How To Become a Radio Amateur",

i note:

The tube choice, 2x 6AQ5, seems kind of odd to me. I'd think the detector would more likely be a 6AU6 or 6BA6,

rather than a power tube. And the output tube wouldn't really need to be that large either, something like a

6AK6 would be fine.

There is NO volume or gain control, only regen control. Not so good.

The coils are low-inductance for the bands chosen – that is, the tuned circuit, for stability, is intended to be high-C.

Even so, the text says the receiver will probably not be useful above 40 meters (7 MHz) band. (They mean not

useful, for CW reception, because of stability, on the upper Novice band of 21 MHz.) The top coil tho, does tune up

to something like 30 MHz.

From: Hubert Miller
Topic: 26184 Message: 26184

The booklet text says the receiver will be not so useful for CW on the higher bands, but still good for AM signals there and

will work a speaker on many signals. That means there’s a lot of audio, as you’d expect from a 6AQ5. Imagining using

headphones with this receiver makes my ears hurt. Yes, many simple regens depended on retarding the regen control

as a sensitivity hence output control, but that also lowers the selectivity, which kind of limits DXability on crowded

bands. The example i have is a faithful copy of the ARRL booklet model and of course i’ll not modify it in any way.

It will be fun to try it out and see just how practical it is to use.

Howard Pyle W7OE in his book “Building Your Amateur Radio Novice Station” actually had a more mechanically and

electrically practical receiver project with the 6EB8 single tube receiver. He dispensed with the vernier drive that the

QST project uses, and used the 2 capacitor tuning system. It does have a volume control, and (he said) it is usable

thru 15 meters. Unfortunately his project receiver and transmitter are a mechanically maximum way to build an

minimalist station. 100 pages of cutting and drilling templates and wiring and assembling subassemblies. What Novice

would look at ham radio as a fun activity if it looks like a 6-month project in metalwork first? This is the absolute

worst Novice how-to book ever. Not only that, but nowhere in the text is the actual tuning range of the receiver’s

3 bands given. The transmitter is a single 6DQ6 but get this, it’s powered by a voltage doubler from a 450 volt

transformer. The key-up voltage is going to be around 1000 volts. Isn’t that fun, boys and girls? He apparently

did this to try to get near the max 75 watt limit, running ~900 volts at 80 mA.
I don’t have ARRL membership at this time. But i wonder if QST reviewed this book and savaged it as it should have

been savaged.

From: William Wood
Topic: 26185 Message: 26185

Greetings Everyone
There is a very similar book to
the one we are studying in the Sams
series, called Amplifier Circuits with
the color flow charts and such. I would
like to beg, borrow or buy this book.
I do see one on ebay for $15, but I'm
such a cheap skate that it would hurt the
pocketbook to do so :) If I could borrow
a copy that would be great. Be happy to
pay postage both ways. Please let me
know if you have one and are willing to
do one or the other of my requests :)
73 fer now
Bill KE9XQ
PS hope to be in town shortly, will see
if the library has a copy, I'm sure they do
not, but the interlibrary loaning system
might bring one up…

IS this a choke and a transformer or is this one transformer made of 3 coils?

I found this GENERAL MOTORS Day-Fan 5077 radio circuit with a set of 3 coils
see picture:
http://www.learnmorsecode.com/regen/gm/GM1.jpg

whole schematic:
http://www.learnmorsecode.com/regen/gm/GM2.jpg

Can anyone tell me what the 3 coil symbols are for and why the middle coil is NOT
connected to the plates.... they are connected to the grids of the preceding stage in the
first four 226 tubes.

Topic: 26187 Message: 26188

They are not shown how you expect air-core transformers to be drawn. Compare these to the iron core transformers in the schematic which are drawn how you expect to see them represented. In any case, I think they have to be air-core transformers for coupling between the stages. The mystery is the center winding--feedback? Anyone familiar with this design?

What are those two headphone shaped gizmos to the right of the 227 tube? Fusible links? Is that a momentary contact switch connected to the plate of the second 226?

This was indeed an early design. They found it necessary to have five secondaries on the power transformer. They even grounded the cores.

It looks to me like an implementation of neutralization, which helps
stabilize a cascade of so many like stages.

So what is the 3 coil device?
IS it really a 3 coil RF air coil inductor or is the circuit so crowded
that they drew a choke coil attached to the plate of each of the first
4 226 tubes?

Topic: 26187 Message: 26192

It's a transformer with two secondaries. The main coupling is from the plate of one tube to the grid of the next. The middle winding provides feedback between plate and grid of the same tube. The way this neutralization trick works is this: The problem is the grid-to-plate capacitance of a triode. You can't eliminate this capacitance, but if you feed back a current exactly out of phase and equal in magnitude to the current through that capacitance, you can cancel its effect. Notice the capacitance in series with that middle winding. If that middle winding provides a voltage that is exactly out of phase with the plate voltage, then the current through that added capacitance is out of phase with that flowing through the tube's capacitance, offsetting its effect.

This technique was developed by Louis Hazeltine, and allowed the TRF architecture to dominate for a long time after the superhet was invented.

Tom

26194. How to improve SSB reception

Yahoo group: regenrx (2016 — 2017)

From: kc2siz@...
Topic: 26194 Message: 26194

I recently build a regen using a 12au7 tube.

The receiver is working. It receives AM well, but it's not so good on CW and it is not good at all on SSB. It does oscillate, but SSB signals remain sounding muffled and unintelligible.

What can I do to improve performance on SSB?

Here is the exact receiver I built:

http://www.vk6fh.com/vk6fh/12au7regen.htm http://www.vk6fh.com/vk6fh/12au7regen.htm

I will be traveling for the next few days and may not see your replies until I get home, but any suggestions will be appreciated.

One thought if the tuning coil is anything like the photo then you might be getting mechanical feedback. The vibrations from the speaker are making the coil vibrate changing the frequency with the audio, this would make it sound muddied.

Bad idea having air tuned coils without mechanical support, the old air inductors used plastic ribs to keep the coil rigid, I would try using a pill container to tightly wind the coil on, and listen with headphones to see if that is your issue.

Thanks Cecil. I did not build it like the one in the photo. I used a coil form that's plugged into a socket, and the coils are held in place with hot glue, so there's a lot more mechanical stability than you see in the photo.

Digging a bit more found TRF details here:

https://en.wikipedia.org/wiki/Tuned_radio_frequency_receiver

and here:
https://en.wikipedia.org/wiki/Neutrodyne

What grabbed my attention was the huge numbers of all those coils
because from a caveman electronics perspective... we can wind coils.

The TRF wiki shows a litz wire basket weaved coil with what looks like
layers of litz wire wound around the finished basket weave coil.
I am wondering if the basket weave is actually two coils or if the
basket weave coil attached to the grid next stage and the other two
coils are the circumference wound coils.

26199. Re: [regenrx] Oscillator Discussions OR Regen Discussions???

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-19 20:32:32 UTC
From: Daniel Donnelly
Topic: 26165 Message: 26199

I have been in electronics for 50 years, both in the commercial field and
for the last few years as an amateur, and have yet to find a book that
really explains all the in's and out's of even the three basic oscillator
circuit.
I am downloading the PDF you sent out and will enjoy reading it
a discussion group would be excellent at bring the practical aspects of
oscillators into view.
Thanks
Dan

Well, what will blow your mind once you get to that point, is that there aren't three basic oscillator circuits -- they're actually fundamentally the same.

I would recommend not worrying so much about taxonomy (Colpitts vs. Hartley vs. Clapp vs. Pierce vs. Armstrong vs.....), as the exercise doesn't teach you very much. It's far more enlightening to understand those oscillators as feedback systems. Then you'll see that you just need enough gain to overcome loss, and that the gain has to be phased right (net zero phase around the loop). That's necessary, but not sufficient. You also need stable amplitude control, and that's where the real complexity comes into the picture.

Thanks Tom;
Yes, I understand.
It has been drummed into me that oscillators are just amplifiers with the proper feedback loops. It's getting the feedback loops AND the ancillary stabilizing circuits to work together that creates the problems.
Dan

Absolutely. The amplitude stabilization part is what trips up most people -- professional engineers and hobbyists alike. Even Bill Hewlett blundered with his famous light-bulb stabilized oscillator (it exhibits stability only by luck). Getting enough gain around the loop is actually pretty easy (unless you're pushing the limits of a technology). Getting the amplitude to be stable is much less easy, as it depends on nonlinear processes. For most, analyzing nonlinear systems is difficult. That's why so many oscillators exhibit squegging, if they actually oscillate at all.

In the context of oscillators used as regenerative detectors, a lesser-explored but very interesting option is to use a separate active device (separate from the amplifier) to limit the oscillation amplitude. By careful design of the limiter stage -- specifically, by using a scale-invariant gain compression law -- it is possible to control certain aspects of regenerative detector behavior that are generally considered to be intractable. In particular, almost all regenerative detectors will exhibit bandwidth expansion above the oscillation threshold, observable as a whitening of the noise as the regeneration control is advanced farther and farther above threshold. This behavior is due to changes in the self-limiting gain compression behavior of the amplifier as we advance the regeneration control farther above threshold; the changing gain compression behavior results in a different ultimate post-regeneration selectivity curve depending on the above-threshold setting of the regeneration control.

But -- and here's the kicker -- if we use a separate and carefully-designed active stage that exhibits scale-invariant gain compression (i.e. the gain compression behavior is the same regardless of the signal amplitude), then the regenerative detector bandwidth *will not change* above threshold, even when advancing the regeneration control (within limits) farther and farther above threshold. This means that we can decouple oscillation amplitude and detector bandwidth. As a practical application, we can crank up the oscillation level quite high to achieve clean direct conversion of CW/SSB signals; normally, this would be inevitably accompanied by a widening of the detector bandwidth. But with the separate limiter stage, even when running at a high oscillation amplitude, we can still independently control the detector bandwidth (via parameters of the gain limiter) to achieve a desired, narrower degree of selectivity.

Furthermore, by using a separate limiter stage and not requiring the amplifier itself to self-limit, the amplifier stage can be kept constantly in class-A operation. This has some subtle benefits like a reduction (to essentially zero) in the frequency shift above the oscillation threshold -- another aspect of regenerative detector behavior that is generally viewed as intractable.

This has all been experimentally verified in practice by vladn at TheRadioBoard. You can read the details here:

http://theradioboard.com/rb/viewtopic.php?t=4680
http://theradioboard.com/rb/viewtopic.php?t=4680
http://theradioboard.com/rb/viewtopic.php?f=1&t=5153
http://theradioboard.com/rb/viewtopic.php?f=1&t=5153

So, there's still room for deeper understanding and improvement of the basic regenerative detector, if we take the time to analyze the underlying processes in detail.

Best regards,

Note carefully that Tom was talking about three particular named oscillator topologies, all of which happen to operate by means of an amplifier in a positive-feedback loop. Not _all_ electronic oscillators use signal amplification, and not all electronic oscillators operate by means of feedback. But any oscillator that can be adjusted and applied such that it qualifies for the label "regenerative detector" will involve amplification within a positive-feedback loop.

From: Bry Carling
Topic: 26206 Message: 26206

Yes indeed - that is a nice design for a transmitter and you can actually run a little more power than
the "novice gallon" with it. For those who wish, you can get the plate voltage up around 500 to 550V with impunityon a decent pair of 6L6GB tubes as Leo Fender does.

The power on that rig can be easily 100 watts DC input or more.

Subject: [Glowbugs] Re: re "Novice Pair" receiver

QST came out with a much better Novice transmitter design in Jan 1957 by Lew McCoy. Uses a parallel pair of 6L6GB excited by 6AG7. Was.titled "6L6GBs in a 2-Stage Novice Rig". The sub-title was "A Simple Band-Switching Unit for 80, 40, and 15". The construction article was also included in the 1957, 58, and 59 ARRL Handbooks as "75 Watts on Four Bands" with the added 20 meter band. Neat piece. Found a nice one at a hamfest and resurrected it. Friend who is a CW maven ran it for ARRL's Straight Key Night (SKN). I wrote the restoration up for the April and May 2015 issues of "The Spectrum Monitor". I believe it was McCoy's answer to what the Heathkit AT-1 should have been since he also had a prior QST article on improving the AT-1.

Rich KB8TAD

Hue wrote:
" The transmitter is a single 6DQ6 but get this, it’s powered by a voltage doubler from a 450 volttransformer. The key-up voltage is going to be around 1000 volts. Isn’t that fun, boys and girls? He apparentlydid this to try to get near the max 75 watt limit, running ~900 volts at 80 mA.
I don’t have ARRL membership at this time. But i wonder if QST reviewed this book and savaged it as it should havebeen savaged."

26208. Oscillator Discussion chptr 2 squegging

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-20 17:27:32 UTC
From: Rob
Topic: 26165 Message: 26208

Well guys.... I got to chapter 2 and the explanation of squegging.
Page 38
http://kid-power.us/book/00020a.jpeg

I thought Tom had a typo for "squealing" until I got to this page 38.

On 04/19/2016 05:01 PM, Tom Lee tomlee@ee.stanford.edu [regenrx] wrote:

26209. Re: How to improve SSB reception

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-20 17:28:15 UTC
From: b_weeber@...
Topic: 26194 Message: 26209

Hello Steve

This sounds like overloading. The 100pF antenna coupling capacitor is rather large as well. Try to reduce the amount of antenna signal by reducing the capacitor to 1-2pF. Then turn the audio amplification up.

If not enough audio, then check here, how to increase the LM386's amplification:
http://www.intio.or.jp/jf10zl/LM386.htm http://www.intio.or.jp/jf10zl/LM386.htm

http://www.intio.or.jp/jf10zl/LM386.htm

http://www.intio.or.jp/jf10zl/LM386.htm http://www.intio.or.jp/jf10zl/LM386.htm 7.How to get 74dB by LM386 lm386.gif LM386 is very popular IC also in Japan. It is used in Radio receiver. The power of it (500mW) is enough for the personal use...

This is Rick, K1WYH. If any of you should run across a Heathkit 12 volt vibrator power supply model VP-1-12, puts out 250v at 60 ma from a 12v battery, I might want to purchase it. Have ordered the manual from ebay. May build one up myself if nothing out there. I want to build up a non-solid state station.
Rick, K1WYH

Hi Rick,

Not to discourage you - If you intend to use the vibrator power supply as a 'daily driver' you should acquire a quantity of whatever model vibrator it uses. Vibrators and selenium rectifiers (solid state) are the most unreliable parts in those supplies. The selenium rectifiers produce toxic fumes when they fail but that won't be a problem for you since they are solid state and banned from your design. They are in serious competition with vibrator contacts for the title of 'most unreliable part'. There are some really robust transistors to tempt you to the 'dark side' in your power power supply. I have some here from the 60s that were used for years in rugged mobile radios and they still do the job.

Other choices are to place your gear on a shelf as working examples of nostalgia but if you use a vibrator power supply a lot it won't be a 'working' example. If your decision about solid state is based on 'surviving' a nuclear attack it won't matter (even if it does survive). There will be nobody to talk to and you will spend all of your time and energy trying to find food along with any other 'survivors' who also have no time to play radio.

If it is for nostalgia - let me wish you the best of luck. Tubes and 'retired' hardware are fun to play with. And don't forget about the dark side and those sturdy transistors. You can always hide the the transistors and make your power supply play a whine-n-chatter.wav audio file for realism <evil grin>.

More about selenium rectifiers: They do not age well. They age sitting on the shelf, and faster in service. I have seen them equally non-conductive in both directions. Used in battery chargers the transformer usually had taps to overcome the increasing forward resistance. Leave the old selenium rectifiers in place "for show," and put silicon ones out of sight. Fie on selenium rectifiers.

It should be possible to convert to a transistor multi-vibrator supply, and you will have a reliable sturdy supply.

I have been working on a boost/flyback converter that should produce voltages for a tube receiver. Getting 250v without a step up transformer of some kind might be tough. Running a power supply with a higher-frequency of rectification is also tricky because it throws false signals into your receiver and probably transmitter too.

It's also possible to make an inverter at the standard 50 or 60 Hz and get a big enough transformer. A transformer rated at 24v center-tapped at 2A should work for you.

Thanks for the comments. I did not know it used selenium rectifiers.
If I do get the Heathkit, I will put in a vacuum tube rectifier.
Antique Electronics has a variety of Vibrators.

Hi Rick,

I don't that *your* vibrator power supply uses selenium rectifiers. Many of them did.You may find that it has a vacuum rectifier already or it may have silicon rectifiers. You should just be aware. I recall or radios with vibrator supplies used a LOT of spares.

In a class I took once upon a time we were told that the vibrators were the most likely source of problems, followed by selenium (if present) followed by tubes, followed by electrolytic caps. I recall that tubes were quoted as having about a five year life expectancy (average) but transistors had been in widespread use for about 20 years and there were no significant failures in normal use. Just reviewing those statistics puts me squarely on the 'dark side'. However, tubes have their own draw and they attract me, too. The tubes I am using have been in service much longer than 5 years. Am I living on borrowed time or is that just my conservative use of those tubes?

73,

Bill KU8H

Bill et al,
Back in the day when I was still a kid (we're talking the mid 1950's here) I used to help out in some Radio/TV shops. The 'usual' car radio had a vibro-pack with an 0Z4 (cold cathode) rectifier. Vibrators were the most unreliable part of the receiver, followed by the 0Z4 (a small metal octal tube).

But whenever the vibrator was replaced it was routine, and HIGHLY advisable to also replace the HV capacitor (1200-1500 Volts) snubbing capacitor across the transformer secondary. In fact, I think that to keep the vibrator warranty in effect it was required to replace it (but 60 years later I don't remember for sure).

I also know that "Snubbing capacitor" wasn't the actual name for that part, but again, memory fails me in that area. . .

Another thing, to provide plenty of audio in a vehicle with windows open (A/C wasn't common), Push-Pull output stages, usually 6AQ5 or 6V6 tubes, but some also had the Loctal equivalents was the usual tube lineup. Tuned RF amplifiers in the front end were also the norm, and in fact more than one person 'converted' a car radio over to use in the house as they usually performed/sounded much better than the AA5 (All American 5) table radio.

Hi Phil,

That's interesting. Your experience is counter to the manufacturer's data (that classroom material) and the data and your experiences don't match my experience (those long lived tubes).

I am stretching my memory too, but I seem to remember it was called a "buffer" capacitor

And as an additional thought, the Motorola "T Power" mobile had a pair of transistors in the power supply, and as far as I could tell, they were reasonably reliable. At least I don't remember any failures in the 5 years or so that I was acquainted with these sets, but I only worked in a small independent shop and did not see the numbers of sets that a "real" service center would see.

Ah, brings back fond memories. The 0Z4 was/is an amazingly efficient generator of broadband noise. You had to shield it and filter its output well if you didn't want your radio to lose several (many) dB of sensitivity.

Hi Rick,

I don't that *your* vibrator power supply uses selenium rectifiers. Many

of them did.You may find that it has a vacuum rectifier already or it

may have silicon rectifiers. You should just be aware. I recall or

radios with vibrator supplies used a LOT of spares.

In a class I took once upon a time we were told that the vibrators were

the most likely source of problems, followed by selenium (if present)

followed by tubes, followed by electrolytic caps. I recall that tubes

were quoted as having about a five year life expectancy (average) but

transistors had been in widespread use for about 20 years and there were

no significant failures in normal use. Just reviewing those statistics

puts me squarely on the 'dark side'. However, tubes have their own draw

and they attract me, too. The tubes I am using have been in service much

longer than 5 years. Am I living on borrowed time or is that just my

conservative use of those tubes?

I remember it being called a "buffer cap" but that may not be correct either. I think it formed a resonant circuit with the power transformer.

26225. RE: [regenrx] Hello the group

Yahoo group: regenrx (2016 — 2017)
Date: 2016-04-22 03:03:30 UTC
From: Charles Moizeau
Topic: 26210 Message: 26225

"Cold Cathode" was what the tube manuals called the OZ4 rectifier. The glass envelope was however plenty warm from that rather evil-looking bluish violet glow.

My only encounter with one of those tubes was the type "BH" (yup, it was called just that) in a scrounged power supply named a "B Eliminator" that weighed nearly 10 pounds and offered DC Voltage outputs at 45, 90 and 135 V. That was in 1943 when electrical stuff wasn't too readily obtainable.

The maximum voltage did the trick to power this nine-year-old's first homebrew receiver (a pair of 6J5s--regenerative detector and audio amplifier), and the advantage of those metal tubes was that they didn't give a tell-tale glow to reveal upon an unannounced bed check that after lights out I was in fact QRV. As for the BH, its glow could only be seen if one looked straight down into the B Eliminator that was next to my bed.

Those unwelcome but thankfully brief interruptions caused me to only miss a few seconds of Inner Sanctum during the brief moment the earphones had been quickly hidden underneath my pillow.

This is interesting. The thread mentions that manually manipulating the AGC voltage as a regeneration control allows for regeneration control that is "very smooth, and without any hysteresis or frequency pulling."

I think it is possible that if the amplifier part of the oscillator is kept constantly in class-A operation (without self-limiting), with the separate limiter stage compressing the gain to achieve oscillator amplitude stability, that the class-A operation of the detector might contribute to the lack of frequency pulling with (above-threshold) adjustment of the regeneration control, due to no Gm change required from the linear amplifier to sustain oscillation of any amplitude (as per vladn's analysis at TheRadioBoard that I linked to earlier).

So I can believe that this scheme with the MC1648 VFO IC could lead to a regeneration control that does not pull the frequency with above-threshold adjustment.

However, the gain compression behavior of the AGC loop is not clear to me and I would guess that it is not scale-invariant (i.e. the gain compression behavior will probably change depending on the oscillation amplitude). Therefore, there will likely be bandwidth expansion as the set is pushed harder into oscillation, as with ordinary self-limiting (class-C) oscillating regenerative detectors. But this is just my guess, and it would be interesting to test. Again, vladn's set at TheRadioBoard used a specially-designed limiter with scale-invariant (and parameterisable) gain compression, so he was able to control the above-threshold detector bandwidth independently of the oscillation amplitude.

Hi Charles,

I'm guessing and LED would have been a serious problem. It's too we
can't get LEDs in metal cases.

As Cecil mentioned, the detector is overloading. That 100 pF antenna-coupling capacitor is too large by a factor of 50 to 100.

If your antenna is outdoors, you should also connect a 1-megohm resistor between the antenna side of the coupling capacitor and chassis to drain off static charges on the antenna. Otherwise that capacitor will pop when the charge on the antenna becomes sufficiently high.

With the Hartley circuit--which this is--the cathode tap on the oscillator coil also gives you a "free" alternative spot to couple in the antenna--a coupling point that in general will apply considerably less of the antenna energy to the detector. So in addition to reducing the value of the coupling capacitor, you can also try connecting the antenna and its coupling capacitor to the cathode tap on the coil.

A few other aspects of the circuit would differ in the hands of a more-experienced designer. For starters, for a less-scratchy regeneration control, I'd add a 22- or 47-uF electrolytic capacitor between the REGENERATION control wiper and common, with negative to common. This should also have the effect of making the detector's AF output vary a bit less with the REGENERATION setting, as the added capacitor _bypasses_ the "cold" end of the detector-plate-load 100-k resistor to ground, pegging the detector load at 100 k. With the REGENERATION control arm not bypassed, you're changing the detector load resistance as you adjust regeneration. Yes, the detector will work without this addition, but adding the bypass capacitor makes the detector's behavior more predictable.

The 10-uF capacitor coupling the AF triode to the LM386 is far too large a value. 10 nF is sufficient.

I'd bypass the 12-V rail with a 100-uF (or greater value) electrolytic capacitor. LM386s can be very prone to introducing distortion and howl if audiolike variations are allowed to ride on its dc supply.

More audio output will be available from the AF triode with, say, 47 k as a plate load instead of 22 k. But with only 12 V on the anode of a tube intended to operate at, say, 45 V and up, your options for improvement there are limited.

Assuming that the receiver suffers from a combination of overloading and audio muffledness, a chief source of that muffledness is AF rolloff caused by the 330-pF capacitor between the detector grid and AF ground (through the tuned-circuit coil). Reduce the value of that capacitor to 100 pF or even 47 pF. (At W9BRD I use 1 megohm in parallel with 100 pF for CW reception. It works fine.)

Another way to make the circuit overload less is to run the detector tube (at least) at a higher plate voltage--say, 90 to 150 V. The more power the detector runs (within limits), the less overloadable it will be.

Best regards,

Dave

Here is an old RCA lesson on Oscillator Circuits.
I know we said today we'd start our discussion on
the chapters in that book, but I think chapter one
was pretty fundamental :) Any thoughts or questions
someone might have? Any ideas or??? If all goes
as planned I hope to present a couple Jpegs during
the week on the subject.

Here's a quick question. Take an oscillator circuit
plain vanilla circuit and tell me how many different
ways you can change it's frequency… ???

Change its L or C or both, and/or change the load impedance connected (even if it's just resistance) across the oscillator tuned circuit.

More interesting question: How many different ways can the L or C or both in a regenerative detector--and therefore its frequency of oscillation--vary by _unintended_ means?

Followup question: How can you minimize unwanted frequency shift by these unintended means?

Best regards,

Dave

From: dawmast@...
Topic: 26194 Message: 26235

The anode loading resistor of 100k can introduce instability when detecting SSB signals or when receiving AM signals at the threshold of oscillating. You would better use this double triode 12AU7 in cascode configuration. See "cascode detector advantages?" at https://groups.yahoo.com/neo/groups/regenrx/conversations/topics/6489.

Topic: 26194 Message: 26236

Yes cascoding the triodes helps...because that makes a synthetic tetrode! See http://www.mif.pg.gda.pl/homepages/frank/sheets/142/6/6386.pdf http://www.mif.pg.gda.pl/homepages/frank/sheets/142/6/6386.pdf for examples of curves for same; in that case the triodes have extended-cutoff grids. (BTW, be sure you're sitting down if you see what 6386s go for as NOS these days...) A snag with cascoding the triodes in this low-supply-voltage context will be that the very low plate voltage then divides across the seriesed-for-dc triodes, and not equally. 6 V is just plain not enough for useful operation with a 12AU7.

So of course I recommend stepping away from the run-tubes-far-below-their-design-voltage fad and operating that part of the set at a realistic plate voltage (90 to 150 V is fine). At that point, it can be realized that cascoding triodes squanders much of the potentiality of a 9-pin socket. That's why I'd use a 9-pin triode-pentode, with the pentode as detector and the triode as audio amplifier.

Note well that running the tubes near 100 V will require some thought as to how to safely drive the LM386, as the AF-triode-to-LM386 coupling capacitor will have to charge on power up, and that charging current will subject the 386 to input overvoltage depending on where the AF GAIN control happens to be set a power-up. A modest series resistor (say, 2.2 k in series with the 0.01-F AF-triode-to-LM386 coupling C) followed by a Zener diode (5 V? 12 V?) should protect the 386.

Best regards,

Dave

Hi all..... I'm curious about a cap shown on Joe's Reflex Regen schematic. On one op amp he has off pin 6 a 1mf electrolytic cap and on the other op amp, pin 6 he has a 1mf cap....I've attached the schematic and have circled the parts in yellow. Is a 1mf cap a normal part? I'd like to build this but can't seem to find 1mf cap in my junk box. I don't think he forgot to add a + to indicate that it was also an electrolytic and unfortunately, Joe recently passed away so I can't ask him.
Tnx....

From: Phil
Topic: 26238 Message: 26239

Hi,
I haven't built the set, but did look at the schematic. I'd have to say yes, 1mF is a normal capacitor and since it's only audio an electrolytic would be fine. In fact, if it were me, I'd use a larger one on the 2nd Op-Amp that's feeding the headset, probably at least 47 uF or more depending on the headset impedance.

And the + leg of the cap would go to pin 6 in each case as the Voltage on that pin would be + to ground.

Topic: 26238 Message: 26241

I played with the image contrast and posted 3 pictures here:
http://www.learnmorsecode.com/joesreflex/index.html

I think those are U not M and mean 1 uF
which mean ONE MICROFARAD

There doesn't seem to a lot of mixed up M N U designations in the
drawing so I would think
that the author wrote his MICROFARAD "U" real fast which gave him that
upstroke heading into the U ...which gave us
the questioning M

But hey... what do I know.... my vision is impaired... so I capture and
enlarge and contrast adjust schematics like these just
to figure them out.

And considering that 1 mF would be 1,000 uF ...that would be one honkin
big capacitor.

1 mF (millifarad, one thousandth (10−3) of a farad) = 1000 µF =
1000000 nF
1 µF (microfarad, one millionth (10−6) of a farad) = 1000 nF =
1000000 pF
1 nF (nanofarad, one billionth (10−9) of a farad) = 1000 pF
1 pF (picofarad, one trillionth (10−12) of a farad)

SO chasing 741 opamp audio circuits shows this:
http://www.rason.org/Projects/opamps/opamps.htm

using 10uf on the output.
As does lots of audio circuits leaving the tone you desire to be
adjusted by using 1uf for more treble and 10uf and higher for more bass.

Just my 2 cents.

In the old days, there was no uF. It was 1mfd or 1mf, and it meant 1microfarad. A picofarad was a mmf (micro-microfaradm sometimes pronounced "mickey-mike"), so the pF didn't exist.

(And while we're at it, there was no Hz. It was a cycle per second, often abbreviated to "cycles".)

Thanks for all of the replies/info. I found the cap code for a 1uf is 105. That should help locating one if I have it in the junk box, otherwise I'll just use the 1uf electrolytic like Phil suggested.

With modern components come some new ways of of disturbing the frequency of an oscillator that uses them. The inductance of a coil with a ferromagnetic core can be shifted by magnetic fields, including those from a speaker or power transformer.
PN-junction-containing devices associated with an oscillator's tuned circuit can shift its resonant frequency when exposed to light, including infrared. This goes for plastic variable-capacitance diodes used for tuning as well as glass switching diodes like 1N4148s, which in some circuits are used as gate clampers (for JFETs). (I've even had hum directly induced in a pentagrid product detector by light from an LED desk lamp. Moving my hand between the lamp and tube made the hum go away. This effect could have happened "yesterday" only with fluorescent lamps, as the thermal persistance of incandescent-lamp filaments irons out flickering that ac would otherwise cause.) Shift or ripple on the control voltage supplied to variable capacitance diodes can cause unwanted shifts.

Best regards,

Dave

Topic: 26247 Message: 26247

Trotting down the path of finding a suitable replacement for 1N34A and other
germanium cat whisker diodes used in old time radio circuits I stumbled across
one circuit that said a D311 was OK to use instead of 1N34A.

So I found an EBAY new old stock source.....
shipping is not free but cost to buy 200 diodes with shipping totals $20

100x D311 Germanium Ge Diodes 30V 40mA Made in USSR NOS

So just for kicks I compared this little black beauty with a genuine 1N34A
in a bare bones simple crystal radio circuit and found that it
definitely worked great.....
as good as any 1N34A ever did in this circuit.

So perhaps D311 will work for your circuits that call for 1N34A diodes
and you can pay a dime for them.

From: Leonard Meek
Topic: 18418 Message: 26252

I just uploaded the schemo for my Mk.21 one tube regen. It's as near as I can remember to the AC regen I built back in the '50's. It uses all the coils I wound for it back then. I don't know how I managed to hang onto them all these years. It works pretty well but it needs a coil for the BC band. Tuning is a little touchy. I haven't tried it yet on SSB.

My Mk.30 is on hold for now. I have a couple hundred small coils that I was planning to use in a band switching regenodyne, but I can't find the right combination of inductances to fit the tracking calculations. Most of them are <1uH, and made for solid state applications. I may try winding my own coils. Gotta hurry though. Time is runnung out.

Leonard

Hello Leonard,

I looked at the circuit of your Mark 21, single tube regen. with great interest. You used a 9001 type pentode. I see that the base connections for this tube is the same as the 6AK5. Have you compared these two tubes in your circuit? This would be interesting for me, because the 6AK5 has a transconductance of about 5000 umhos. The 9001 is lower at about 1100 umhos.

The other point - ability to resolve SSB - is also interesting to me.

Your sets are always interesting!

Les

And, this ripple might even be caused by varying ambient electric fields, such as those produced by the motor of a desktop fan. With my varactor-tuned regenerative receiver, I can place the set near a running fan, and the electric field from the running motor is enough to cause noticeable warble in the received frequency. I found out that my soldering iron also created a hum-inducing electric field. My early tests with varactor-tuned regens were led astray by the fact that my work desk usually has, during development, both the fan and the soldering iron switched on. This caused many hours of frustration until I finally realized the circuit was fine; it was the fan and the soldering iron that were causing the hum.

I re-did coils in two transmit-purposed variable frequency oscillators for this same reason, replacing coils based on ferrous toroidal cores with large air-coil solenoids wound on pill bottles and shielded in large cans. I suspect that ferrous cores could cause phase-shift-induced hum problems even in non-oscillatory tuned circuits when high orders of frequency multiplication are involved.

And another noise-introduction mechanism: The ceramics used for capacitor dielectrics are commonly piezoelectric, allowing caps using them to act as microphones. I recall some early synthesized HF and/or VHF ham transceivers were subject to audio howling at high AF output levels due to acoustical feedback from inboard speaker through ceramic caps in their synthesizers.

26257. Regen based upon the VCO part of an MC1648 VFO IC.

Here I have a regenerative receiver which is based upon the VCO part of the MC1648 IC. T1 which is an RF preamplifier also provides a constant current through L1 for the stabilizer LED D1. D1 provides the bias for both the oscillator part around T3 and T4 and the detector part with T2. T5 is an adjustable current source for regeneration control by changing the standing current through T3 and T4. P2 is the coarse regen control, P1 is the fine regen control. Regeneration control is smooth. Vcc is 9V.

Topic: 18418 Message: 26258

Les, I tried the 6AK5 and noticed a slightly improved performance, but that was before I took care of a couple of other problems. I know the gm of the 6AK5 is higher, but so is the input and G-P pF's. With only a single tube, the gain is not huge. The reason I used the 9001 is that's what was in the original ciecuit, probably in the August 1953 issue of Radio Electronics magazine, which I haven't been able to locate. The set seems to work very well on MW, and yesterday was pulling in 17M stations (Aus or NZ) with enough volume to require reducing the AF gain. I don't expect this set to be a world beater though. It's just one of the many projects I've wanted to tackle from books like Radio for the Millions.

From: Leonard Meek
Topic: 26259 Message: 26259

Les, I just checked and my Mk.21 has the 6AK5 in it. I thought I had put the 9001 back in. I tried it again with the 9001 and it didn't live up to the hype. I guess more gm's is better than less input pF's. So for the Mk.21, scratch 9001 and write 6AK5. The only downside is the heater current for the 6AK5 is 0.175 mA vs 0.15 for the 9001. Not serious, but it does cause a little more volt drop across the 22 ohm dropping resistor.

Noting that copper wire coils do not stick to a magnet.....
like a copper penny doesn't stick to a magnet......
and that a magnet will induce current in copper and
we can make copper create magnetic flux by adding electricity.......
having said all of that.....

IS THERE ANY ADVANTAGE OR DISADVANTAGE TO WINDING OSCILLATOR TANK COILS
FOR RF
regen purposes using wire that WILL stick to a magnet... like KANTHAL
resistance wire?

Is it good or bad to wind inductors with iron wire?

https://en.wikipedia.org/wiki/Inductor

I never really thought of it before because we think of wire as copper
wire....
until now that I stumbled onto resistance wire..KANTHAL... readily
available for
vaping..... which will stick to a magnet.

The problem I see with that approach is one of "Q". That is, the
inherent resistance of "resistance wire" would definitely decrease the
"Q" of the coil, which would have an effect on bandwidth if it were part
of a tuned circuit. Also, "IR" losses would lower the gain. This is
one reason that Litz wire is often used in higher inductance coils that
, it reduces the "RF Resistance" due to "skin effect" at RF. IMO, in
most cases you would want to keep circuit stray losses to a minimum.

Another consideration is that, although a stationary permanent magnet has no effect on a copper-wound coil, it can change the inductance of a coil wound with ferromagnetic wire. If you want to build a lossy PTO, I guess that's one way to do it, but...

Short answer: Copper is your friend.

Arnie, the Russian equivalent of the 6AK5 tube is what that German “Retro Radio” kit uses, with a 2-transistor amplifier.

As i recall, the tube is run at effectively, 15 volts B+ (9 volts + stacked 6AK5 filament voltage). We discussed that kit

some time back here, like a year or two by now. I think the schematic shows up online somewhere.

One odd thing is that the grid leak resistor was returned to B+, not to B- ground.

I have the kit, just never yet got around to building it. It’s on the list.

Of course, with the conventional higher B+ of 100 or so, it would have more output; as Leonard reported, maybe doesn’t

even need any following audio amps.

> So does this mean we should black tape or shrink wrap varicap diodes and glass 1N4148 diodes?

Yes, if they're exposed to light and they play a role in setting or clamping voltages or currents associated with RF oscillators, including the tuning diodes for same, and AF amplifiers. (Shielding in a light-tight box the circuitry that contains them also works.)

I rediscovered this issue after having solid-stated a Collins PTO with a JFET equipped with a 1N4148 gate-clamping diode. I was listening to the signal from the out-of-its-can oscillator in a workbench receiver when the dinner call came. As I snapped off the bench light, I heard the pitch of the received signal change. Light on, one pitch; light off, slightly different pitch. Woo hoo! I could have rigged a keyed LED to shine on the clamper diode for modest FSK...

And that was with an incandescent bench lamp. Had the lamp been fluorescent or LED I would already have been chasing down why the oscillator sounded rough...

Here are some resources that touch on the topic of diode photosensitivity:

"Glass diodes may see the light -- and hum" (http://www.analog.com/en/education/education-library/raqs/raq_jb_glass_diodes_may_see_the_light_issue45.html)

"LEDs are Photodiodes Too" (http://www.analog.com/library/analogdialogue/archives/48-08/raq_108.html)

More general document on photodiodes: (http://www.analog.com/library/analogdialogue/archives/48-08/Photodiodes.doc)

And hummy light may also directly affect vacuum tubes other than phototubes/photomultipliers. During experiments with various heterodyne detector hookups last year, I discovered that an LED desk lamp induced strong hum in a 12A8GT pentagrid converter (used as a product detector, with output at AF) a foot away. Putting a hand or book between the lamp and the tube made the hum go away. (In that particular 3023-kHz-centered circuit I settled on a high-C 12A6 Hartley regenerative detector instead and have been using it ever since. Another win for oh-so-modern metal tubes...)

Best regards,

Dave

Dear amigo REGENRX LIST MEMBERS ;
I do not have that German regenerative Retro Radio
circuit diagram and building instructions...
What I am looking to open up the possibility that
many of the now only 2 meters band Cuban hams
go on the air on the HF bands, is a receiver that
will meet the following criteria.
1. Must use common earbuds type of earphones as they are plentiful
locally (so high quality high impedance
headphones are ruled out !)
2. It may use from 12 to 150 volts DC , coming from
several different already tested power supplies
3. The radio must provide 40 meters band , with
very good bandspread between 7000 and 7125 kiloHertz, the most used
segment here in Cuba for national
NVIS propagation mode contacts
4. It must provide good quality SSB voice and CW
reception... with easy to tune feature ...
5. Vacuum tubes preferred... Russian 6AK5 and 12AT7
equivalents..i.e. clones !!! that are locally plentiful
6. Transistors; Preferred NPN common types like the
Russian KT315 , a sort of 2N2222 , also locally plentiful
7. To use as many parts recycled from Compact Fluorescent Light Bulbs,
like 1N4007 diodes, 1000 pF polyester capacitors and 22 mfd 250 volts
electrolytics
8. Point to point wiring as no printed circuit virgin boards are
available...
9. Coils wound on PVC pipe...
10. Air spaced variable capacitors recycled from AM
Soviet radios , like VEF206 and SELENA... 365 pF
dual section, and for bandspread the variable capacitor from the FM
tuners of those now defunct radios ...
As you see amigos.... the limitations imposed on the design are
plentiful, but I am optimistic that
we can come ahead with a viable receiver, later to
be followed by a CW transmitter in the 5 to 10 Watt
class.
What do you think about this ?
Your opinions will be most appreciated...
73 and DX
Your amigo in sunny La Habana, Cuba
Arnie Coro
CO2KK

Hello Leonard,
The question, "To what degree does the TYPE of detector influence the performance of a regen. radio?" has always interested me. For example, does a pentode work more effectively as a detector than a triode?" Or "How does a triode detector compare with a JFET detector?"

Your set answers the question "How does a low Gm pentode (say 1100umhos) compare with a higher Gm pentode (the 6AK5 has a Gm of about 5,000)?"

It's an interesting answer, because it always seemed to me that there was NO WAY a humble triode could perform in the same class as a pentode (like the 6AK5). The twinplex is a very "neat" receiver, after all. Your observation, it seems, suggests the opposite. You compared the 9001 pentode (Gm = 1100) and the 6AK5 (Gm = 5000). The only variable in your experiment WAS THE DETECTOR Gm, and you say that the 6AK5 is clearly better. Oh - and the heater current. I remember reading somewhere that triodes seemed to work better when the filament supply was throttled.

Your set answers another question. For some years I've read people put the question, "How would an acorn 'tube' perform in the role of detector?" We know now, at ;least as far as the 9001 is concerned, because the 9001 has the same characteristics as the (acorn) 954 - the only difference is the envelope.

So - thank you (and your Mk21) for answering two questions that have interested me for a long time!
You collection of home-brew radios is quite interesting!

Good-day Prof Coro!
How nice to read your posting. Your proposal focuses on details of the circuit, but I remember James Millen wrote that construction was the key to a reliable and stable receiver. He gave practical tips about wiring - for example - the filaments must be wired using twisted pairs, and that the 'tube' must not be enclosed in a "loop" of the filament circuit. We all know these things now.

To return to the topic of construction, since this is the key to obtaining a stable SSB receiver. I ask, what facilities to you have for sheet-metal work? After this I turn to the circuit.

I suggest either a two-tube Regenerodyne or a two tube "Jones" superhet, using a 12AT7. I propose the B+ supply would be 90V DC. I propose that the AF stage be followed by an emitter follower; if the left and right ear-phones were wired in series the effective impedance would be 60+ ohms. In series with a 100 ohm resistor this would not lose too much volume and could be driven by a single NPN transistor. I do this in a set I have. I take the signal from a 6AK5 detector to an emitter follower (hi-Z input impedance and lo-Z output impedance). This eliminates the difficulty of impedance matching. In your case the match won't be perfect, but it will work.

To better illustrate my point about circuit design; consider the receiver the Polish underground used in WWII - the Nelka or the Pipstock. This used a 12K8 (frequency converter to 1700kHz IF) and 12SJ7 (detector) to provide CW communication between Warsaw and England.

My final question. Do you have a good supply to 10k (or 100k) potentiometers? This, with a 1N4001 diode, makes an effective band-spread circuit.

Finally, if some-one could give you just one plastic bag of "goodies" you could use a wider range of components than you write about here. However, getting a bag of goodies thru the post may not be easily done. I remember I sent a small parcel of crystals to your address - and somehow they got "lost" in the mail. - v. sad!

Hi there Prof,

I don't have any copies of those receiver projects. You did mention low power transmitters (this is wandering a little into an off-topic but tangential area). You also mentioned harvesting parts from CFL bulbs. You mentioned the diodes and the caps but you ignored the pair of power FET transitors. Those make good finals for transmitters in the power range you are looking for - or even a little bit more. Look at class D or class E designs using those. They are smaller and more efficient than something like a 2E26 - an RF power valve that can give us 25 watts if we lean on it hard enough.

73,

Bill KU8H

Les, please don't take my results as definitive. Many other factors affect the performance of the detector. The 9001 may not have been in optimum condition. The 6AK5 had a Tektronix label on it. I didn't check either tube on my TV3B tube checker. Other things like layout, plate load, turns ratio between coil windings, B+ voltage, etc. all play a part. There are 1000's of regen schematics published, but they are all basically the same circuit; an amplifier with positive feedback. Generally speaking though, it does seem that higher gm's are better in some applications. I'm sure other, more experienced members will clarify this.

Leonard

Hola amigo:
Will like to see the circuit diagram of your audio amplifier that uses
the emitter follower.
As stated previously, we must rely on the omnipresent
earbuds.... to which the new generation is now so well
adapted too (they seem to be glued to the earbuds
most of the time, with all the associated dangers that
this practice implies)
I am planning on preparing 10 kits , including the schematics in printed
form , and a long list of the
do's and dont's when assembling the receiver, as
those making them may be located at remote towns
and villages with no other radioamateurs homebuilders
fan in the vecinity... They usually have a 2 meters FM
handie talkie with a home brew external antenna and
their DX range is as far at the best repeater they can
access...
BUT , when they go on the air on 40 meters they can
take part in my own SOLDERING IRON AND MULTIMETER SUNDAY ROUNDTABLE,
7115 KILOHERTZ, where I
answer their questions and help them debug what they
build...

From: kc2siz@...
Topic: 26194 Message: 26278

Thanks to all of you for your suggestions. They have definitely helped. I am now able to demodulate SSB signals much better. I notice though that I need to have the RF gain turned almost all the way up and the AF gain turned down as low as possible. That's not normally the way I operate, but it is working.

I also noticed that the receiver seems unable to go into oscillation in the lower 1/4 of its tuning range. My guess I'll have to play with the location of the tap in order to fix that. It probably needs to be a little closer to the center of the coil.

That can be my fun project for the weekend!

Steve

26279. Fwd: RE; The single vacuum tube regenerative: A radiotechnology wonder

Yahoo group: regenrx (2016 — 2017)

Si amigos ! A well designed and well built single vacuum tube regenerative (preferred to be made with a pentode tube) maybe aptly described as a radiotechnology wonder.

My favorite circuit uses screen grid regeneration control for very smooth transition of the location along the operating plate current/voltage curve...

I do not endorse the use of very low plate and screen voltages for the optimum performance radio...

You do need at least 60 volts on the plate to really make it operate at the best possible settings.

In actual practice, the Hartley circuit has IMHO its slight advantages over the use of a throttle capacitor at the plate feedback coil, but the difference between the two circuits is really subtle.... except for the fact that you do save an air spaced variable capacitor (throttle control) traded for a good quality (yes it must be a really good quality regeneration control potentiometer) smooth acting control.

Build it like if you were assembling a classic vacuum tubes VFO... so that it will be a mechanically extremely solid radio.

As regards to the air spaced variable tuning capacitor there are again, IMHO, two excellent although hard to find and expensive options: The BC221 or LM or Russian CH4-1 frequency meter capacitor and dial assembly, and as a second choice a BC457,458 or 459 variable VFO tuning capacitor and front dial....

More to follow... about tuned circuits and power supplies I do respectfully invite comments from our distinguished RegenRX list members

Yes,

Invar (an abbreviation of invariable) is great stuff. The plates in the variable capacitors used in the VFOs of the command transmitters, widely used in WW2 fighter aircraft, were made of it.

Recently Prof. Arnie Coro praised those capacitors for use in regenerative detectors. He probably knows about their invar plates.

Well, probably not fighters. Bombers, sure. I think B-17s had sets of 'em, for instance.

> Recently Prof. Arnie Coro praised those capacitors for use in regenerative detectors.
> He probably knows about their invar plates.

Snag with old Command-set capacitors is that 70+ years on their wiper contacting can be pretty flaky. The receiver caps seem to be better in this regards than the transmitter caps, in my experience so far.

Never, ever pull plates!

Best regards,

Dave

Yes, here in RegenRx a commenter found the 6SL7 to work better.

On the other hand, in his fine Twinplex pages beginning at
http://faculty.frostburg.edu/phys/latta/ee/twinplex/twinplex.html
http://faculty.frostburg.edu/phys/latta/ee/twinplex/twinplex.html , Greg Latta, AA8V, reports that he finds the 6SN7 to have the edge.

It's also worth considering that the tubes differ in amplification factor (circa 20 for the xSN7, 70 for the xSL7) and also in transconductance. Considering that operation as a regenerative detector and operation as a Class A audio voltage amplifier (with a pair of high-Z headphones or equivalent as its ultimate plate load) are very different applications, there's the possibility that locking oneself into using two identical triodes (by using a two-identical-triodes tube like the xSN7, xSL7, or similar miniatures) may be suboptimal for one or both functions. After all, the reason the Twinplex came into existence was to leverage the Type 19 twin-triode Class-B-power-amplifier tube, the identical sections of which had a common cathode. 85 years later, having a multitude of single and dual triodes available for experimentation, we are not so bound. One might even use an xSN7 for one function and an xSL7 for the other, using only one unit of each. Here the (true) parable of Fabre and the processionary caterpillars may be found to apply. For those wanting to experiment with a more modern Class-B common-indirectly-heated-cathode dual triode, there's the 53 [2.5 V heater] and the 6.3-V-heater 6A6, 6N7, 6Y7, and 6Z7, among others.

Best regards,

Dave

Les, the most apparent thing I've noticed between the 12AT7 and 12AU7 is smoother regen control with the 12AU7. It doesn't jump into oscillation as sharply as the 12AT7. But the 12AT7 seems to have a little more gain. Of course, this could be because of variations in the tubes characteristics. I've had different results with identical tubes, sometimes from the same manufacturer. It seems pointless to design a circuit for precise performance when there's no guarantee that the tubes will have the exact characteristics listed in the data sheet. I use ballpark calculations and don't worry about IMD or third order intercepts. All circuits need to be tweeked after building anyhow. I used to work on analog computers. Whenever a tube or other component was changed, we had to do a complet realignment to get the errors back to acceptable limits.

Hello Leonard,

I'll watch for others to comment on this point.
I recall comment about the performance of a xSL7 vs the xSN7 here.

These two tubes were compared in a twinplex. The difference (as I recall) was not obvious, but there was a preference for the xSL7.

Hi,
I built a receiver very similar to Peter Parker's using a 7.116 MHz CR and a 16-116p variable capacitor.
It works fine, but the frequency range is only 81 KHz (7017-7098KHz).

Does anyone have a suggestion for extending the frequency range (other than switching in CR's of different frequencies?)

I could easily put two CR's of the same frequency in parallel to see what happens, but I have not done so yet.
There does not seem to be a lot of information on manipulating CR circuits.

Fortney

I’ve heard of successful
attempts at this, never tried it
but I would think it will not hurt.
Let me know if it works for you
if you do try it.

Just dawned on me you’re talking
about the crystal resonator… Some
people like myself sometimes don’t
read the subject line :) Of well, let me
know tho if the two side by side makes
any difference, still want to know.

I’ve not tried any of these ideas yet,

Dear Professor Coro

Now and then I have thought about sending some components to you use in community qrp projects. However, before the recent welcome warming of diplomacy, I did not see a method for mailing to Cuba. Is there a method now, and an address, we in the US could use to ship items to Cuba that you could use in education/ham projects.

From: Rob
Topic: 26296 Message: 26296

This is sort of under the heading of WHY ARE WE HERE

I'm here playing with radio circuits and examining HOW to build radios
from scratch
.....especially regenerative receivers.....
because a year ago I was building 100 crystal radios to donate to a
kids gig and found out that
1N34A crystal radios were the footing to start with...not the desired
architecture to build
radios that really worked.

Upon further research I stumbled onto the history lesson that for the
first 90 years
of short wave radio there were a lot of people building their own radios and
the industry supported "MAKERs" and DIY people like us amateur radio
operators.
The abundance of radio magazines telling you exactly how to build your own
receiver from parts you made from scratch .... India ink resistors...
tin foil and wax paper capacitors....
is not something our kids would ever learn from NINTENDO.

So along those line I found very detailed educational material that
explains tube radios
for true beginners ...farmers building tube radios
and
a lot of very in depth transistor radio instructions... using math I
never saw in high school.

So here ..... when we play with the best of both worlds.... building
tube and transistor radios......
I am searching for , and attempting to settle on, one radio to kit, one
pile of parts to buy real cheap,
so when my radio club does a kids gig I can hand a BAG O PARTS out that
is pretty much guaranteed to
be a successful receiver.

The 40 meter 7.16 ceramic resonator regen was attractive because all the
parts are pennies.
Nothing high price or rare.

Does this transistor receiver work any better or worse than a tube regen?
Does a newbie really care if this receiver works any better or worse
than a tube regen?

So then I wonder if ANY of the parts in the 716 regen are restricted
from sending to Arnie.

http://www.learnmorsecode.com/716/index.html

When I buy transistors I spend $15 and bulk purchase 1,000 components.
1N4148 is $10 for 1,000 diodes.
AND much less for SMD parts.

What State Department restricted countries... embargo.... law says
that I can't
send Arnie a box of parts that cost me $30 so he can teach radio
electronics to his students?

I can't seem to find any laws about such low value like $30 of components.

Hello Rob,
I have no idea why I can't send a few quartz crystals to a Professor in Havana, but I sent a packet of "nice" frequency crystals 2 days short of 2 months ago and nothing has arrived yet. My idea was to send an inconsequential handful of crystals to test the system. They cost a few cents each - but to Arnie they could be quite useful in a regenerodyne.

All this doesn't make sense to me. Arnie is just "doing the right thing" - but methinks the "system is agin 'im".

Les

Hi,

You are defaming mud. There is good reason why we rag on the internet as unreliable. State department rules (and most other things) are subject to change. If you do find those rules posted on the internet be sure to check the publishing date as the first step. Internet performance is so poor because outdated, inaccurate information is left out there for us to find and try to use. We should be able to contact the State Department directly about this question. Use Google to find a new pair of shoes.

73,

Bill KU8H

Not so much variation in characteristics of the same tube design, but different tube designs. The 12AU7 has an amplification factor of 20, and the 12AT7, 60. So the 12AU7 is similar to the xSN7, and the 12AT7 is similar to the xSL7. This matters, especially for audio-amplifier use, because triodes of significantly different amplification factors require significantly different bias for best results. Both will "make noise"; both will let you "hear signals", but the fact that their manufacturers _designed and made them differently_ means that they are best _applied differently_ for best results.

What you're saying about variations in active-device characteristics (for a given device type) is entirely true--IF those device-to-device variations are not ironed out through the use of negative feedback (https://en.wikipedia.org/wiki/Negative_feedback https://en.wikipedia.org/wiki/Negative_feedback). Through the use of negative feedback, for instance, I can build the same op-amp-based AF amplifier across millions of instances and, assuming all passive components are within tolerance, achieve the same performance from instance to instance within a dB or so v frequency. Likewise, I can build my favorite BJT post-mixer amplifier over and over with the same component values, and assuming all passive components are within tolerance and the BJT I use has at least enough gain to make the negative feedback work properly--the design takes that into account--EVERY instance I build of that circuit will have the same gain, frequency response, and dynamic range.

Negative feedback was so revolutionary that when Harold Black attempted to patent it in the early 1930s--when radio and AF circuitry was generally built to get as much gain out of a device as possible--the patent office rejected it as absurd. ("What? _Throw away_ gain on purpose? Surely, you jest!")

As for hand-waving about the immateriality of intermodulation distortion and dynamic range concerns, when these become so bad that they interfere with what you want your circuit to do, you pay attention to them and fix them. Regenerative detectors generally have such generally narrow dynamic ranges that some of the easiser-to-notice IMD issues that a wide dynamic range reveals (such as the generation of fake signals that sound like they're on

the air but aren't) don't occur before the detector falls over. On the other hand, regens block (desense) easily and are relatively easily frequency-pulled by strong signals, especially (for CW reception) at lower receiving pitches; of these, frequency-pulling dynamic range can be very materially improved by operating the detector at a lower frequency (say, at IF) and/or with high C to L ratio (detector tuned circuit reactances of 100 ohms or less at resonance). It turns out, for instance, that the simple act of reducing the signal input to a regenerative detector to the point that the antenna-system noise floor just overrides the detector's own internal noise _profoundly_ improves that detector's resistance to overload and frequency pulling. (Why not just do it like they did it "in the old days"? Because now we know more. If we learned to wash our surgical instruments between operations to reduce the risk of infection, we can learn to knock down a regen's signal diet so it works better.)

Some of us find fun, for instance, in understanding the fact that even a simple classical regenerative detector that uses a vacuum-tube triode uses a combination of positive feedback and negative feedback at the same time. The positive feedback (coupling of the tube's RF output back to its input, via a tickler coil, cathode tap on the tuned circuit, or Colpitts capacitive voltage divider from cathode to grid, makes the tube oscillate. The negative feedback (which provides an automatic-gain-control voltage at the tube grid) comes from the tube's self-rectification of its input signal in its grid-cathode diode, resulting (from voltage drop across its grid-leak resistor [on the order of 1 megohm] charging its grid filter/coupling capacitor [on the order of 100 pF in many circuits]) in an AGC voltage that lets the tube self-regulate how strongly it oscillates. Every classical tube regen ever built includes these features "free of charge"; they're just there and they operate. Only when one of these mechanisms malfunctions--for instance, causing "fringe howl" at and just above critical regeneration in a triode detector--do we pay attention to it and willfully take steps to investigate and fix it.

And BTW, could we include an _oscillating_ device in a negative feedback loop to regulate _its_ behavior, make it less subject to the vagaries of tube-to-tube or transistor-to-transistor variation? Yes; that's called a phase-locked loop, and it's why modern radios no longer include manual tuning capacitors for tuning. Could a regenerative detector be embedded in within a PLL? Sure, at least to some degree. The work and the result would be more complicated than happens to interest me, but others might find that challenge to be right up their alley.

Best regards,

Dave

26300. Why 6AQ5s in the Novice Special receiver?

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-01 12:23:41 UTC
From: david.newkirk@...
Topic: 26300 Message: 26300

This weekend I was reviewing Don Mix's Novice Special regen (June 1956 QST) and its matching converter (October 1956 QST) and came across the author's discussion of why he used a 6AQ5 for the set's detector:

"A more-experienced amateur may question the use of a power tetrode as the detector. Several of the 'hot' r.f. pentodes, such as the 6AK5, 6CB6 and 6BJ6, were tried. It was found that tubes of this type were highly critical as to feedback. It was practically impossible to control regeneration satisfactorily (at least by the screen-grid method) over any appreciable frequency range, and the detector was prone to jump into v.h.f. parasitic oscillation. An even more disappointing development was that the signal output was pitifully small, and even less than a moderate signal would block the detector. The 6AQ5 solved all of these difficulties."

An xV6 or xBW6 would also serve; they're electrically the same tube as the xAQ5. In my superhet-regens I'm currently I'm using 12A6s--also "power tetrodes"--as detectors. The 12A6's lower heater power compared to the xV6/xAQ5 reduces warmup drift, and its metal envelope makes shielding the detector tube oh so easy. Regulated powers the sets' heaters for less hum and (for the detectors) better frequency stability.

Best regards,

Dave

Thanks for the explanation, Dave. I knew you sould clear up a lot of misconceptions. I still use a "wonder if this will work" kind of designing, but it's definitely more fun to get something to work on purpose than accidentally.

Leonard

> a little more gain. Of course, this could be because of variations in the tubes characteristics.

Not so much variation in characteristics of the same tube design, but different tube designs. The 12AU7 has an amplification factor of 20, and the 12AT7, 60. So the 12AU7 is similar to the xSN7, and the 12AT7 is similar to the xSL7. This matters, especially for audio-amplifier use, because triodes of significantly different amplification factors require significantly different bias for best results. Both will "make noise"; both will let you "hear signals", but the fact that their manufacturers _designed and made them differently_ means that they are best _applied differently_ for best results.

What you're saying about variations in active-device characteristics (for a given device type) is entirely true--IF those device-to-device variations are not ironed out through the use of negative feedback (https://en.wikipedia.org/wiki/Negative_feedback). Through the use of negative feedback, for instance, I can build the same op-amp-based AF amplifier across millions of instances and, assuming all passive components are within tolerance, achieve the same performance from instance to instance within a dB or so v frequency. Likewise, I can build my favorite BJT post-mixer amplifier over and over with the same component values, and assuming all passive components are within tolerance and the BJT I use has at least enough gain to make the negative feedback work properly--the design takes that into account--EVERY instance I build of that circuit will have the same gain, frequency response, and dynamic range.

Negative feedback was so revolutionary that when Harold Black attempted to patent it in the early 1930s--when radio and AF circuitry was generally built to get as much gain out of a device as possible--the patent office rejected it as absurd. ("What? _Throw away_ gain on purpose? Surely, you jest!")

As for hand-waving about the immateriality of intermodulation distortion and dynamic range concerns, when these become so bad that they interfere with what you want your circuit to do, you pay attention to them and fix them. Regenerative detectors generally have such generally narrow dynamic ranges that some of the easiser-to-notice IMD issues that a wide dynamic range reveals (such as the generation of fake signals that sound like they're on the air but aren't) don't occur before the detector falls over. On the other hand, regens block (desense) easily and are relatively easily frequency-pulled by strong signals, especially (for CW reception) at lower receiving pitches; of these, frequency-pulling dynamic range can be very materially improved by operating the detector at a lower frequency (say, at IF) and/or with high C to L ratio (detector tuned circuit reactances of 100 ohms or less at resonance). It turns out, for instance, that the simple act of reducing the signal input to a regenerative detector to the point that the antenna-system noise floor just overrides the detector's own internal noise _profoundly_ improves that detector's resistance to overload and frequency pulling. (Why not just do it like they did it "in the old days"? Because now we know more. If we learned to wash our surgical instruments between operations to reduce the risk of infection, we can learn to knock down a regen's signal diet so it works better.)

Some of us find fun, for instance, in understanding the fact that even a simple classical regenerative detector that uses a vacuum-tube triode uses a combination of positive feedback and negative feedback at the same time. The positive feedback (coupling of the tube's RF output back to its input, via a tickler coil, cathode tap on the tuned circuit, or Colpitts capacitive voltage divider from cathode to grid, makes the tube oscillate. The negative feedback (which provides an automatic-gain-control voltage at the tube grid) comes from the tube's self-rectification of its input signal in its grid-cathode diode, resulting (from voltage drop across its grid-leak resistor [on the order of 1 megohm] charging its grid filter/coupling capacitor [on the order of 100 pF in many circuits]) in an AGC voltage that lets the tube self-regulate how strongly it oscillates. Every classical tube regen ever built includes these features "free of charge"; they're just there and they operate. Only when one of these mechanisms malfunctions--for instance, causing "fringe howl" at and just above critical regeneration in a triode detector--do we pay attention to it and willfully take steps to investigate and fix it.

And BTW, could we include an _oscillating_ device in a negative feedback loop to regulate _its_ behavior, make it less subject to the vagaries of tube-to-tube or transistor-to-transistor variation? Yes; that's called a phase-locked loop, and it's why modern radios no longer include manual tuning capacitors for tuning. Could a regenerative detector be embedded in within a PLL? Sure, at least to some degree. The work and the result would be more complicated than happens to interest me, but others might find that challenge to be right up their alley.

Best regards,

Dave

You COULD use Google, but why beat around the bush? For U.S.A. senders, go to
http://about.usps.com/publications/pub699.pdf
for the (confusing, tricky, exception-ridden, and verbose) rules. If you do look at this article, it appears pages 14 and 18 are noteworthy. Books and such generally get a free pass.
BUT - things like electronics parts would come under the rules for "scientific equipment". It APPEARS to me for mailing such, you need to use a U.S. government online submission form available via the (no fooling!) Census Bureau's "Automatic Export System" to get an "International Transaction Number" which you will write on your postal form 2796 which goes on the parcel. So it does LOOK do-able if you're patient and willing to jump through all the hoops. I'm sure you will encounter some entirely confused people at your local post office which will also add to the general headache of trying to do this. Nevertheless, i am willing, myself, to try it, later this year, when i will have more time. Assuming, of course, someone in the recipient country would like a small package of MOSFETS, ICs, variable caps, and such.

Addendum to my previous: one way to circumvent the tedious process is to pay to an overseas seller, like in Hong Kong or Canada or Europe, and have them

send the parts or items to Cuba.

Of course, that doesn’t help to thin out our own full “junk boxes”.

If by MOSFET you mean "dual-gate MOSFET," an option to try if a dual-gate part is not available is to connect two JFETs in cascode. This works because in effect a dual-gate MOSFET is two triode MOSFETs in cascode, and because the difference between a JFET and a MOSFET is largely unimportant in small-signal applications at HF and below.

huh?

You lost me there with "two triode MOSFETs in cascode"

I thought Arnie's use of MOSFETs he was re-purposing out of power
supplies was
for transmitter final PA output transistor circuits.

And since IRF530 power mosfets are used in 50 watt RF amps sold on EBAY
...whole kit for $18....
I looked into prices and found IRF530 power mosfets sell for 35 cents now.

Hey ARNIE... what would you build with IRF530 POWER MOSFETS if you had a
bunch of them come your way?

Hi All,

I posted the following to the Zenith TransOceanic Group (Radio I'm presently working on), but it is also applicable to homebrewing things like Regens etc.

****

Right now I'm in the process of overhauling a Zenith Royal 7000 Transoceanic for a friend. I've done some of them in the past, so I'm well familiar with them.

The 'Big two' capacitors were pretty much a piece of cake. Snip the capacitor out, clean off the terminal posts and install the new ones, which incidentally are MUCH smaller in size. I buy Radial Lead 'Lytic caps in bulk, which is ideal for connecting to the solder lugs, even though the originals are axial lead devices.

NOTE: I've also bought large assortments of "Poly" Caps, Ceramic Disks etc in bulk, MUCH cheaper than onesies and twosies, and I have them when I need them.

So far so good. Then I got to a couple where I snipped the lead off the capacitor, leaving enough lead to do a nice neat "hook" connection with the original leads. I REFUSE to try to remove the original leads from those hollow Solder lug things (like small hollow tubes) that Zenith used to group a bunch of connections together. The likelihood of heat damaging something is too great.

To make the "hook connections" I gently scraped the original wire and tried to tin it. It just didn't seem to want to "tin" nicely, and I want nice, clean professional looking solder joints (I take pride in them).

****

THEN, I thought of the Solder Flux pens I bought when I was building my Softrock SDR receiver. It has a lot of small surface mount IC's etc and I wanted to be SURE everything got soldered up nicely, or cleaned up if I needed to solder wick some connections (I find the flux on solder wick is sometimes dried out and not completely effective, I first coat it with the 'pen', works VERY well). When I ordered the Softrock, I also ordered two of he Flux-Pens (MG Chemicals Rosin Flux Pen Cat. No. 835-P) from Amazon. There are a LOT of different kinds on the market, MG Chemicals is a reputable company. Two turned out to be way overkill, I'm still on the first one, the other package unopened.

So I first gently scraped the wire, then used the Flux-Pen and coated the wire, waited a few moments and then tinned it. It did an absolutely WONDERFUL job! The solder connections look really good.

****

The beauty of the Flux Pen is it doesn't leave a lot of residue and isn't nearly as messy as trying to use a small bottle of Rosin Flux! I have found it useful in a number of projects.

This is a simplified version of my direct conversion receiver, using a common NPN silicon transistor as the product detector... By using this simple product detector I avoid the need for toroid ferrite cores required for a four diodes product detector.... All I know is that it works quite well. It needs a stable VFO ... my design uses three NPN transistors and benefits from the
¨cold styrofoam oven ¨ where it is kept at constant temperature !!! No DDS or PICs etc....
The audio section, not shown here consists of two filters, one for voice and the other 700 Hz peak tuning for CW... then several possible options for the audio power amplifier...
This receiver is quite good for daily use, but it will not make you a CQ CW Worldwide Contest winner, because it lacks the selectivity required for such high QRM environments.
A good friend tells me to use FETs like 2N3819
or MPF 102... but the ones I now have are 3N152
that are described as IGFET, that have proven difficult to ¨tame¨....
The RF choke at the plate of the product detector is just a ferrite bar pile wound with many turns
of thin wire....that works as well as a NOS factory built ¨reference¨ 2,5 mHy National Corp choke...
Comments from my amigos are invited, and apologies for not using regeneration on this
direct conversion receiver....

Hi amigo !
Just got five IRF510 that a friend from VE land
brought... Looking now for a circuit of a reliable
linear amplifier built using two of the IRF510's.
I have a toroid core salvaged from the video
cable of a monitor that now we know here that works for the broadband
output transformer, as other Cuban hams have already built linears using
MOSFETs recycled from computer
UPS supplies with such ferrite cylindrical cores!!!
We can wind power transformers for 24 or 48 volts supplies that can
provide 10 amps or more, using the rectifier diodes from the recycled
UPS computer back up units !!!

Hi Prof Coro,

I have a circuit that uses the IRF510 on 80m. I never tried this circuit on 40m!

The circuit is a single board double side-band (DSB) transmitter, consisting of VXO, buffer, balanced modulator, driver and then two IRF510 devices operating in push-pull to drive a 50 ohm load.

The bad news:
(1) This is designed, built and tested (to a small degree) on 80m only.

If no-one supplies a more likely circuit I will post it among the "files" - but only then. On my work-bench it drives a 10 watt load. The circuit operates from a 24V DC supply.

I can say the IRF510 is one of the few candidate MOSFETs for this type of application. The input capacitance is approx 135 pF (according to the spec sheet). Most devices have more input capacitance, and driving a higher capacity load at frequencies above 80m is difficult.

Les

Device Input "C" - gate to source
IRF510 135
IRF520 330 pf
IRF620 135
IRF620 400pF or above.

Oscillator stability is not about the particular circuit used, but about how the circuit is built and used. But it's true that many hobbyists tend to use JFET VFOs more than BJT VFOs for some reason. So here's a circuit that works just fine, and if built with NP0 capacitors and allowed to stay powered up will be quite stable. For best stability, use an air-core coil rather than a ferrous-cored one.

WEll, It was I. I have and use two dual triode regens (one upstairs and one down stairs) as a ham BTW , not a SWL. On one I now use a 12sl7 now simply because I can use a small solar panel and a 12 volt gel cell from a 2 M candlepower lantern to keep the heater power alive without thinking about it but essentially the characteristics are the same. If you are listening to broadcast stations or are a strongest station only Cw operator then the 6sn7 (or 12sn7) will be fine for you. I originally built mine for a 6sn7, truth be known, from the Linsday book. However if you are doing low power ops and like me , live not near any one else operating that mode then the 6sl7 or 12sl7 makes a noticeable difference in low level signal work. I used to think, like I am sure many of you do as well, the difference was neither here nor there but when push comes to shove I found myself reaching for the SL tube every time. I also built the regen from the 1943 ARRL handbook and use it with the matching breadboard transmitter from the same book on 80M. I didnt have the tube it called for so I subbed a 6sl7 and it also works well. Every once in awhile because I always double check myself I will pop in a 6sn7 or a 12sn7 just "to be sure" I wasn't lying to myself. I am as convinced as I can be that the difference s worth it and now can see no good reason not to use the SL from the git go. It is my understanding one was designed to amp voltage and one designed to amp power to put it crudely but in understandable terms. Probably if you could buy a tube which was one side 6sl7 for the regen detector and the other side 6sn7 for the audio amp you would have the best of both. If you aren't using it for low level ham QSOs it probably doesn't matter. You will never notice what you are missing.
BTW I also have a cathode modulator that uses a 6sl7 or 6sn7 in the speech amp. I use a dynamic mic in that circuit which is low output compared to a single button carbon mic with battery bias. I have poped a 6sl7 there as well. The difference is quite noticeable . So for me when dealing with low level inputs (weak signals or weak input) I now choose the 6sl7. If I have strong input and need power I use a 6sn7. That is my story and how I got there. Not a hill I want to die on but it has been my experience and no what I strongly beleive dirived from that. If you must use the 6sn7 because George Grammar or Sir Percy Maxim III said so go ahead. I am not built that way. Results trump every thng here.

From: rlpend@...
Topic: 26316 Message: 26316

Hi,

I built this pretty much according to his schematic. I used 47K instead of 220K and my tuner is 16-116pF and I added a preamp before my Islander amped speaker.
It works just fine, but the tuning range is only 81 KHz.
I lifted the ground lead and that moved the frequency range up 4 KHz, but did not expand it.

Aside from switching in CR's is there a way to expand coverage? I may place two CR's in parallel to note the effect, but have not done so yet.
In his You Tube he says he has about 50% more frequency coverage that my radio has.

Has anyone else built one of these?

Thanks,

Fortney

It seems to me that most of the discussion on "SL" vs "SN" involves simply swapping the tubes in a given circuit. But since the tube electrical characteristics are quite different, wouldn't some circuit components need to be changed to make a more realistic comparison?

Leonard

Hello Jerry

For me the circuit works well, one Resonator should be enough. My range reaches from 6960 ... 7130 kHz. What i need, is a band spread. What happens exactly with your circuit, does the oscillator stop? Please tell your tuning range.

Best regards,
Bernd

KB8TAD published notes about a two tube regen. receiver using a 6SN7GT and 6V6GT. In this set the 6V6GT has the role of detector, and he drives a small speaker from the 6SN7GT. Thus he reverses the normal role of these two tubes.

Here is the link: http://www.ohio.edu/people/postr/bapix/Regen_HB.htm

Using this set for the first time he reported,

"I connected an output transformer and speaker to the phone jack and
proceeded to power it up with the little Heathkit power supply. The
set did not work well with the 6F6. The tube was extremely microphonic.
Finding nothing out of the ordinary in a very simple regen circuit, I plugged
in a 6V6 as originally intended. After [warming up] the set came to life.
Tweaking the 3 to 9 pF antenna trimmer (near yellow clip lead) brought
the noise level up a bit from my 80 meter antenna. I was surprised at
how well the little set worked. I listened to a number of SSB transmissions
and some CW."

and later

"With filaments starved a bit and feeding an output transformer
and speaker, the set performed well on 80 meters with about 60
to 90 volts of B+ at a current draw of about 4 to 5 milliamps."

He reported the remarkable observation that the set delivered "useable speaker volume" from a 12V supply. I guess this may be useful if the only source of power was a 12V battery, but one wonders about this crazy notion of running "tube radios" at such a low voltage, when 60 or 90 volts can be easily got, and offers much better performance.

But your topic was beam tetrodes in the role of detector. I return to that. We all have our innocent little fantasies. Since reading KB8TAD's article (and more recently your posting here, Dave) I've always wanted to build a set using a beam tetrode in the role of detector. Maybe your article will be the final push I need to get out the chassis punch!

Your point that you got greater stability using a 12A6 (with filament dissipation of 1.9W) in place of the 6V6 (filament dissipation of 2.83W) is interesting.

Did I remember correctly that you wrote the 12A6 was moderately microphonic?

Les

Les wrote:

> Did I remember correctly that you wrote the 12A6 was moderately microphonic?

Yes -- that in a 1700-kHz detector a few years back, when the 12A6s I had to choose from at the time were predominantly of RCA manufacture. Since then I've acquired a few handfuls of Ken-Rad 12A6s, and find them to be no more microphonic than any other tube. (Even the RCAs could be improved by doubling a thick rubber band around the middle of their envelope--but ultimately I think the superiority of the Ken-Rads is more an issue of better internal support. The RCAs seem to bong at a particular pitch in a way that the Ken-Rads don't.)

I'm glad to recommend the 12A6 as a detector. My BGCD Regenerodyne (http://dpnwritings.nfshost.com/ej/pictures/pictures1.htm http://dpnwritings.nfshost.com/ej/pictures/pictures1.htm) uses one in a Hartley detector at 3023 kHz (+/- 10 kHz, as its IF is modestly variable behind the set's crystal-controlled front end) and provides excellent results. (The BGCD also uses a 12A6, cathode-switched by a 2N7000 as described in http://dpnwritings.nfshost.com/ej/hybrid_mixer/ http://dpnwritings.nfshost.com/ej/hybrid_mixer/ , as its mixer.) Because the BGCD includes a 2N7000-as-variable-shunt-resistor-based RF gain control, I just plain don't have to adjust the BGCD's regeneration during operating periods. I just set it comfortably above critical regeneration and leave it, and adjust the RF input if signals become uncomfortably loud. My ears complain before pulling sets in!

And BTW considering that the BGCD also uses two 12J5s (metal, please, for better shielding), one for its grounded-grid IF buffer and the other for its AF output preamp, and that metal 12J5s aren't that common, I've just determined that a triode-connected 12SJ7, which tube is cheaper and more available than the metal 12J5, works just as well as the 12J5 in these two applications.

Best regards,

Dave

For use as a detector, generally not. As AF amplifier, yes, as the xSN7 and xSL7 are covered in different tables in the Resistance Coupled Amplifiers section of the RCA receiving tube manuals, meaning that the two tubes should be biased differently (assuming cathode bias, requiring somewhat different values of cathode-bias resistor) for a given application.

That said, just swapping out tubes is a valid comparison for a given set of components. In such comparisons, one is not necessarily finding which tube is "better," but which of the two particular tubes tried is better _in that circuit, with that set of components_. The results _may_ be extendable to multiple individuals of the compared types.

Extra credit for characterizing exactly what's meant by "better" and "worse." For instance, I happen to not care in the slightest how my detectors work for broadcast reception--that is, in "AM" mode, when they're not oscillating. I use my regenerative receivers mainly for Morse code reception in two-way amateur-radio operations, and only very limitedly for SSB, and then only for listening to VOLMET weather broadcasts at 3485 and 6604 kHz. (Sure wish Gander would clean up that distortion...)

I have played around with low voltage regenerative detectors and tried several tubes. Among the decent were 12V6, 12L6, 12DQ6, and 12CX6. The 12AW6s I tried didn't want to oscillate. One of the best tubes I tried was 12CN5, which was sensitive and liked to oscillate anywhere I needed. The problem is that it uses 450ma at 12v for its enormous cathode.

My best Regen ran at 24v and used a 12AT7 and 12AU7 in a 1v2 configuration. I could use it up to 7 or 8 MHz although the coils I wound for it made oscillation tough on the higher frequencies.

I may try again with the 12CN5. I have almost a dozen of them. It is a tube no one seemed to ever want.

I suspected as much, Dave, but I wanted to hear it from you. I'm not a ham so I don't listen to much CW. I do like to be able to get SSB occassionally, and even CB sometimes. I always start with local AM atations and try to get some of the outside islands, or even Samoa (at 540KHz). It's surprising how some tubes will work well in one band and not so much in others. I assume that to be a function at least in part because of the interelectrode capacitances.

Very interesting! The 12CN5 is one of that short-lived class of tubes designed to be sufficiently transistorish (12.6 V heater, 12 [16] or 30 V plate/screen max, depending on the type) to be used as part of hybrid (tube/transistor) designs, when acceptably good/robust transistors were available to make AF power, but transistor RF performance was meh. So in that range we have RF/IF amps, a converter tube or two, triode-diode(s), and a dual triode (12U7) or two--and we have the 12K5, a "space charge" power tetrode (actually works like a triode, because its Grid 1 is not for control but as a high-current accelerator to make the thing draw more plate current) designed to drive AF power transistors for automotive radios).

Yes, that's quite a heater drain--the same power drawn by the heater of a 6L6, only at 12.6 V, I guess for the purpose of achieving relatively high transconductance with only 12.6 V on its plate. So if you're using the tube for a CW/SSB regen, you'll want to locate the tube a hair farther than you might away from the tuned circuit so less that 5.7 W worth of heat gets to your frequency-determining components, even adding suitable ventilation (if the receiver is in a box) so the heat builds up less (and takes longer to build up). (In experimental receivers here I've found even the less-drastic heater-power difference between, say, a 6SN7 (0.6 A at 6.3 V) and wired-for-6.3-V 12AU7 (0.3 A at 6.3 V) to make a noticeable difference in warmup drift in a given radio.

And 12CN5s only a buck or two on Ebay. As you've guessed, that revolving-blue-light-special price comes from their relatively fleeting, limited application. More goodies for us, cheaper!

More "12 V on the plate" experimental candidates are listed in Jeff Duntemann's writeup at http://www.junkbox.com/electronics/lowvoltagetubes.shtml
http://www.junkbox.com/electronics/lowvoltagetubes.shtml .

A plate detector would make a decent mixer, with both frequencies fed into the grid through an appropriate resistor network. So, if one were trying to make a superheterodyne or direct conversion receiver, this type of receiver would work well.

My experience with using such low-voltage tubes as regenerative detectors is that you'd do well to follow them up with a tube audio amplifier. The high impedance of the grid circuit will ensure the detector tube goes into oscillation when it needs to. An LM386 amplifier, having an input impedance of ~25-50K, could prevent oscillation when called upon.

High perveance tubes, such as the old television sweep tubes, work well at low voltages because they are designed to conduct much current at lower voltages. One of the first tube receivers I built used a 12DQ6 detector and a 12DK7 audio power amplifier. A 120-12v transformer served as a plate load and worked well enough.

"I'm glad to recommend the 12A6 as a detector." - Dave Newkirk, W9BRD

I'm changing the topic slightly from 6AQ5 to "beam power tubes as detector". While I'm fascinated with the idea of using beam tetrodes as a detector in a Jones Superhet, I'll resist the temptation to try a new idea before I finish the set I'm presently working on here (in Aus). I began building this set because Prof. Coro wrote favourably about it here. But he described a 'straight' regen set, whereas I prefer a Jones superhet. I use a pentode mixer (6AK5) followed by a 6AK5 detector. After this I have emitter follower to provide a high-Z buffer to the detector. In your "writings" (Dave) I seem to recall you recommend a "tube" to buffer the high-Z output from the detector. (I looked, but couldn't find this point.) I chose to use an emitter follower circuit - mainly because it's easy to build, and MUST work.

This emitter follower provides a conveniently low-Z signal to drive an audio amplifier - and bipolar transistors are well suited to this task. (As an aside - someone here asked me about using this circuit to drive 32ohm earbuds. I'll provide that after I make some measurements to show my circuit is well designed, and not simply parts thrown together in a hurry.)

I can't provide any comparison between the "standard" Hartley detector and the "beam tetrode" detector. I haven't built the latter. Prof Coro's notes led me to the Hartley-6Ak5-pentode detector. He recommended using 36 Volts for the B+ supply; reading his more recent comments I'm not sure he holds that view about a 36V B+ any longer. I CAN say his observation that the Hartley-pentode circuit combined with screen grid regeneration control (as distinct from "tickler") gives silky smooth regeneration. I don't need a "fine" and "coase" regen control - or an expensive variable capacitor. Just a garden variety 20k carbon pot. (If you read this, Prof Coro, I'd like to send you the circuit I drew. If you see any deviation from your design I'll be pleased to re-draw my circuit to meet your spec. I'd like to publish it here - under your name, of course. It is, after all, your "baby". I'm sure many others will be interested to duplicate your success.)

Returning to your Goodman-BI superhets (Dave) - where the 2N7000 modulates the mixer - I looked at your notes (and newer circuit) and conclude that this is a more efficient way to inject the L.O. signal into the mixer than the the setup you show in Fig 7 on this - http://dpnwritings.nfshost.com/ej/goodman_receiver/ - page.

This (Fig 7) is more or less the circuit I use in my receiver, but I plan to use the 2N7000, as I wrote a moment ago.

The other circuit I find interesting is the Polish "spy" radio, the Pipsztok. This is a Jones superhet, using a 6K8 freq. converter and then a 6SJ7 as detector in a very conventional Hartley circuit - rather like the circuit Don Mix published in QST 1956. (I compare only the detector - not the design of the two receivers). This (the Mix design) is the common 0-V-1 regen receiver, but completely unconventional in the use of a 6AQ5 in both stages. Don Mix controls regeneration using a 50k pot in the screen grid circuit. Completely conventional.

The AF stage is the interesting point of difference. Mix used a second 6AQ5 as the AF amplifier; this drives either a speaker or phones. The pipsztok has NO AF amplifier - the detector drives hi-Z phones directly! Both circuits are, according to my view, amazing! How can Don Mix get enough gain to drive a speaker? How can the Poles match the output "Z" for a pentode detector to 4k headphones? Sure, the 6K8 may give a gain of 4 or 5, but this can't match the gain of x15 or x20 from an AF amplifier, and in these minimalist sets, the microvolt signal levels need all the gain they can get. It's 1450 km (or for those who prefer - 900 miles) between London & Warsaw. Even on 40m that's good going for a two tube receiver, and for these fellows, their life hung on a thread! 25% of all underground radio operators in Poland "got a bullet" - one way or another. So - performance mattered. They didn't want to spend more time than necessary 'on air'.

So I don't understand either Mix or the Pipsztok approach. How did Mix get enough gain to drive a speaker? How did the Poles get sound from phones that were mismatched by a factor of (I guess) 10 or 20?

I DO understand that the underground would seek to minimize battery drain. I DO understand that a third tube would increase the load on the battery by 50%. I DO understand that these fellows were unimaginably clever (they broke the enigma code, after all!) and I'm confident (without proof) that they tested the benefit of a third tube (as AF amplifier) and discarded the idea. I just don't understand the physics behind their final circuit design. Maybe some-one here can explain how a detector running (probably) less than a mA plate current from a good B+ supply can properly match the impedance of head-phones.

So - the 6AQ5 makes an interesting detector - comparable to the 12A6. It's just that there are quite a few unsolved mysteries in how people extracted the performance we know they got from these circuits and components.

26336. Mk.21 Mod 3c

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-07 04:20:43 UTC
From: Leonard Meek
Topic: 26336 Message: 26336

I just posted the Mod 3c version of my one tube Mk.21. I tried an A53 audio coupling xfmr in the mod 3b but the increased gain seems to have picked up a bad hum, so I went back to RC coupling in the Mod 3c. The 7809 VR is now a 7812, which gives a little more drive to the 2 inch speaker. The detector plate load resistor is increased to 200K, and the LM386 input is zenered as Dave Newkirk recommended. I found that running the LM386 off raw DC befor the VR wasn't the cleverest thing to do. The chips I was using were N-1's, the 12V version, and the raw DC was 14.5V. I may have smoked a couple of them running them that way. Another thing I found with the 9001 is it's very microphonic. Maybe that's just the one I was using. I was too lazy to dig out my 9001 stash to find out. Anyhow, the 6AK5 works just fine. The set is better suited to use headphones, but I like speakers.

Hello Leonard: Looking at the zeners across the input to the LM386 - what do they do? Clip spikes that might kill the chip? That's Q1.

Q2. You're using a tickler (Armstrong) coil and screen grid voltage to control regeneration. How smooth? Silky smooth?

What can you hear on this?

About amigo Les's REGENERODYNE

Dear amigos; Les use of a mixer ahead of a regenerative detector is what Gary Johanson and yours truly claim to be a REGENERODYNE RECEIVER, i.e. a superheterodyne receiver that instead of using a straight diode detector or a product detector, uses a fully adjustable regenerative detector.
When carefully and properly done coupling between the mixer stage and the regenerative detector is achieved... the sensitivity and selectivity that can be achieved with the detector tuning around 2 to 3 megaHertz is remarkable.
Collins Radio designs using variable IF after a crystal controlled converter at the input is second to none as regards to performance....
The abundance and low cost (no use for the audio fools fanatics) 6AK5, 5654 , 6ZHE1P tubes and their transfer function as the screen grid voltage is moved around makes them ideal for a 2 to 3 megaHertz regenerative detector. Recently a friend found at an old radio repair shop a box full of 6BZ6's by Toshiba of Japan, and they do have more gain than the 6AK5, but the regeneration control performance is not as sweet and nice as with the 6AK5...
Nevertheless they can be used on a straight regenerative as more gain is available at higher frequencies like the 28 mHz amateur band and the horrible 27 mHz ¨ Citizens ??? ¨ band that by the way makes an excellent DX propagation indicator for band openings as there is a lot more activity between 26 and 28 megaHertz than what can be presently heard on the 10 meters band most populated segment 28.0 to 29.0 megaHertz.
Please amigo Les, send your circuit diagram and it is going to be my pleasure to take a nice look at it...
Never forget that the use of regulated DC applied to the filaments of the regenerative detector tube and if possible the first AF amplifier stage is a very good idea !!! I also found out that running the 6AK5's filaments at 5.7 volts makes them work very well...
Just add a 1N4007 diode to the earth leg of a 7805 and you have 5.7 volts... but it you add two 1N4007's the filament voltage will increase to 6.4 volts... still within perfect operational values....and possible of use with slightly worn out tubes !!! No need to go to 6.4 volts with my 6ZHE1P's that are of an extremely high quality ....
About the plate voltage for the regenerative detector, you certainly

will get more gain
while running 50 and more volts ...but as aircraft flight manuals say ¨
never to exceed¨ 140/150 volts... and better yet keep the plate voltage
around 100/110 volts (VR105's still found ??)

Les, there's a voltage spike from the detector at turn on from the solid state rectifier. Dave Newkirk recommended putting zeners acros the LM386 input to protect it. I also found that there are more than one version of the '386: The LM386 N-1 is a 12V max version. The LM386 N-4 can take 18V max. Another thing I discovered was the coils I was using were the ones I originally wound on 4 pin tube bases for the regen I built back in the early '50's. I followed the instructions religeously in the magazine article, which put the tickler winding next to the grid end of the tank coil. Regen control was nervous at best. I tried my newer coils wound on standard coil forms with the tickler coil on the ground side of the tank coil, and the sensitivity is better and regen control is smoother. I think now that I've squeezed as much out of this circuit as I can, and it's time to move on.

This MK21... is this based on a radio article that explains a complete build?

I've found circuits using 5 VOLT 1N751A zeners in front of MPF102 Jfets to protect from spikes
when plugging a guitar into a pre-amp.
This MK21 Mod 3C circuit shows 10V 1N758A.
Can I substitute those 1N758A diodes with my 5 volt 1N7541A diodes or would that let the magic smoke out of the LM386 ?
Would I hear anything different in this circuit if I used 1N7541A diodes?

> The LM386 N-4 can take 18V max.

What I was talking about was that using transistors or similarly low-voltage devices downstream of tubes, with coupling/blocking capacitors keeping the relatively high dc from the plate of the last tube stage from getting to the input of the first solid-state/low-voltage device, endangers the low-voltage devices because the coupling capacitor must charge on power-up.

Yes, this tend to be worse with power supplies using solid-state rectifiers because their output voltage comes up rapidly, as there's no rectifier filament/heater to heat. The magnitude of the surge is also the greater for the fact that the tubes that will draw current from the supply take the greater part of a minute to heat and come up to full current usages--a problem that designers of power supplies even for tube gear must face, as the (usually) directly heated tube rectifiers come up to heat much more rapidly that the (usually) indirectly heated tubes they power.

And so that's why I suggested putting Zeners across the _input_ of the first solid-state device that's downstream of the coupling capacitor. (I assume that the input circuitry of that device includes resistance to ground capable of serving as the charging path for the current through the blocking/coupling C.)

That said, however, I would not assume that the "voltageness" of, in this case, the LM386N (-1 v -3 v -4 variants) has anything to do with the device's ability to tolerate voltage surges at its _input_. Those ratings are about _supply_ voltage. More to this point, I see that the Texas Instruments spec sheet for the 386 lists in its "Absolute Maximum" section "Input voltage: +/- 0.4 V." 0.4 V!

Hmm, a SPICE analysis of how much voltage temporarily appears at the junction of, say, a 0.01-uF capacitor in series through a 10-kilohm resistor to common (10-k AF GAIN control set to max at the input of an LM386) that's suddenly connected to, say, 250 V, would be instructional.

Also very useful would be for someone with a scope or suitable high-Z audio voltmeter to give us an idea of how much max AF voltage appears at the grid of the first audio stage downstream of a vacuum-tube detector. (I have neither.)

And BTW, we should consider that the above scenario actually overloads (in the "optimum load value for maximum voltage gain" sense) a vacuum-tube voltage amplifier that drives an AF GAIN control of 10 kilohms or less. Vacuum-tube voltage amplifiers provide the most gain when driving loads (in the form of the grid resistor of the next stage) many times higher in resistance than the plate resistor of the driving stage. What we should really be doing

to better interface a high-plate-voltage vacuum-tube detector or AF stage to a lower-impedance load is use a cathode, emitter or source follower to drive that 5-k or 10-k AF GAIN control---preferably a cathode or source follower, as these especially can be designed to exhibit the high input impedance appropriate as the load for a vacuum-tube detector or amplifier. When this is done, voltage-surge protection will still be necessary at the interface between the last vacuum tube and the first low-voltage device downstream. The level at which to clamp would best be set after investigation of the AF and surge voltages to be expected at the interface point.

Best regards,

Dave

Well, duh. We don't need a circuit simulator to analyze the worst case, as the worst case is the voltage that appears across the AF GAIN control when the supply voltage hits with the coupling capacitor discharged. A discharged capacitor initially acts like a short circuit for dc, so we can analyze the peak dc voltage across the AF GAIN control merely be calculating the dc voltage drop across the control.

So, for instance, assume a detector plate load resistor of 150 kilohms and an AF GAIN control of 10 kilohms. Seriesed--as they are for dc applied to the power-supply end of the 150-k detector plate load resistor---they add up to 160 kilohms.

Also for instance, assume a detector plate supply level of 250 V. So when that voltage suddenly appears at the supply end of our detector's 150-k plate load resistor, it appears across the 160-kilohm series combination of that resistor and our 10-kilohm AF GAIN control, with the interposed coupling C temporarily acting like a short circuit.

Only 10-kilohms' worth of that drop--10/160--appears across the AF GAIN control. That equates to 0.0625 times 250, or 15.625 V. That's much higher than the 0.4 V absolute maximum the LM386 can tolerate, so we need to keep it from getting to the input of the LM386. If our AF GAIN control happens to be set to zero or an intermediate value that allows no more than 0.4 V or to to be applied to the LM386, we luck out for this power-up event. If not, the LM386 input is likely damaged such that the device can't work.

Shooting from the hip, I suggested Zener diodes, at the time knowing neither the LM386's input limitations nor the magnitude of the voltage surge to expect. Considering the low (0.4 V) absolute max of the LM386 input, I think that a forward-conducting silicon diode (cathode to ground) between the AF GAIN wiper and ground is a better idea.

A 1N4148 or 1N4152 silicon switching diode (voltage drop, 0.6 to 0.7 V) should suffice. 250 V across 150 k results in only 1.7 mA of current flow, so even in the worst case the current through the protective diode would be much lower than the part's average forward current max of 150 mA. 0.6 to 0.7 V is more than the LM386's absolute max, but it would likely provide useful protection. A germanium diode (voltage drop, 0.3 to 0.4 V) would get us closer.

In installing these diodes causes noticable audio distortion, however, it's back to the drawing board. I'm glad that tubes are more forgiving!

All of this said, BTW, we are actually overloading (in the sense of "too low a load resistance for maximum gain") the vacuum-tube stage that drives the LM386, if that stage is acting like an AF voltage amplifier with its output taken from the plate via a blocking C.

For max gain, a tube so configured (as a resistance-coupled amplifier) needs to "see" a next-stage input resistance that's considerably higher than the value of its plate dropping resistor. Yet we commonly see 5 k or 10 k suggested as the AF GAIN control max resistance to use with LM38x-series AF amplifier ICs. So to best interface a tube detector or amplifier with such a lower-impedance low-voltage stage, we should interpose a cathode, source or emitter follower for impedance conversion. A cathode or source follower would be better than an emitter follower, as these can be configured to exhibit the high input resistance that the preceding vacuum-tube stage requires for maximum voltage gain.

Best regards,

Dave

Thanks, Dave. Most instructional, especially the last paragraph. I wondered about the values of the plate losd resistor and the input resistance of the following stage. I'll had to see if I can include an emmitter follower. The 12 and 18 volts I was refering to were supply voltages. It was important in this because the DC voltage I first connected the 386 to was 14.5 volts, and I may have damaged a couple of the chips.

What I was talking about was that using transistors or similarly low-voltage devices downstream of tubes, with coupling/blocking capacitors keeping the relatively high dc from the plate of the last tube stage from getting to the input of the first solid-state/low-voltage device, endangers the low-voltage devices because the coupling capacitor must charge on power-up.

Yes, this tend to be worse with power supplies using solid-state rectifiers because their output voltage comes up rapidly, as there's no rectifier filament/heater to heat. The magnitude of the surge is also the greater for the fact that the tubes that will draw current from the supply take the greater part of a minute to heat and come up to full current usages--a problem that designers of power supplies even for tube gear must face, as the (usually) directly heated tube rectifiers come up to heat much more rapidly that the (usually) indirectly heated tubes they power.

And so that's why I suggested putting Zeners across the _input_ of the first solid-state device that's downstream of the coupling capacitor. (I assume that the input circuitry of that device includes resistance to ground capable of serving as the charging path for the current through the blocking/coupling C.)

That said, however, I would not assume that the "voltageness" of, in this case, the LM386N (-1 v -3 v -4 variants) has anything to do with the device's ability to tolerate voltage surges at its _input_. Those ratings are about _supply_ voltage. More to this point, I see that the Texas Instruments spec sheet for the 386 lists in its "Absolute Maximum" section "Input voltage: +/- 0.4 V." 0.4 V!

Hmm, a SPICE analysis of how much voltage temporarily appears at the junction of, say, a 0.01-uF capacitor in series through a 10-kilohm resistor to common (10-k AF GAIN control set to max at the input of an LM386) that's suddenly connected to, say, 250 V, would be instructional.

Also very useful would be for someone with a scope or suitable high-Z audio voltmeter to give us an idea of how much max AF voltage appears at the grid of the first audio stage downstream of a vacuum-tube detector. (I have neither.)

And BTW, we should consider that the above scenario actually overloads (in the "optimum load value for maximum voltage gain" sense) a vacuum-tube voltage amplifier that drives an AF GAIN control of 10 kilohms or less. Vacuum-tube voltage amplifiers provide the most gain when driving loads (in the form of the grid resistor of the next stage) many times higher in resistance than the plate resistor of the driving stage. What we should really be doing to better interface a high-plate-voltage vacuum-tube detector or AF stage to a lower-impedance load is use a cathode, emitter or source follower to drive that 5-k or 10-k AF GAIN control---preferably a cathode or source follower, as these especially can be designed to exhibit the high input impedance appropriate as the load for a vacuum-tube detector or amplifier. When this is done, voltage-surge protection will still be necessary at the interface between the last vacuum tube and the first low-voltage device downstream. The level at which to clamp would best be set after investigation of the AF and surge voltages to be expected at the interface point.

Okay, Dave, it'll be a source follower. The power switch is on the AF gain control, so the wiper is at the ground end of the resistance at turn on.

Well, duh. We don't need a circuit simulator to analyze the worst case, as the worst case is the voltage that appears across the AF GAIN control when the supply voltage hits with the coupling capacitor discharged. A discharged capacitor initially acts like a short circuit for dc, so we can analyze the peak dc voltage across the AF GAIN control merely be calculating the dc voltage drop across the control.

So, for instance, assume a detector plate load resistor of 150 kilohms and an AF GAIN control of 10 kilohms. Seriesed--as they are for dc applied to the power-supply end of the 150-k detector plate load resistor---they add up to 160 kilohms.

Also for instance, assume a detector plate supply level of 250 V. So when that voltage suddenly appears at the supply end of our detector's 150-k plate load resistor, it appears across the 160-kilohm series combination of that resistor and our 10-kilohm AF GAIN control, with the interposed coupling C temporarily acting like a short circuit.

This MK21... is this based on a radio article that explains a complete build?

I've found circuits using 5 VOLT 1N751A zeners in front of MPF102 Jfets to protect from spikes
when plugging a guitar into a pre-amp.
This MK21 Mod 3C circuit shows 10V 1N758A.
Can I substitute those 1N758A diodes with my 5 volt 1N7541A diodes or
would that let the magic smoke out of the LM386 ?
Would I hear anything different in this circuit if I used 1N7541A diodes?

Hello Leonard: Looking at the zeners across the input to the LM386 - what do they do? Clip spikes that might kill the chip? That's Q1.

Q2. You're using a tickler (Armstrong) coil and screen grid voltage to control regeneration. How smooth? Silky smooth?

What can you hear on this?

Les

26350. Mk.21 Mod 3d

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-09 23:32:15 UTC
From: Leonard Meek
Topic: 26350 Message: 26350

And now for something entirely different.

I just uploaded the final upgrade of my Mk.21. Dave Newkirk recommended a source follower between the detector and the LM386 chip, so I threw one together (litterally) and stuck it into the underside of the chassis. It made quite a difference. The selectivity has improved, and this evening I'll find out how it works with both sets of coils. Right now it's a one tube, one transistor, one IC hybrid set. I guess I'm cheating a little, but you can't argue with success. I scoped the input and didn't see any voltage spikes over a few millivolts at turnon so I omitted the zeners. Time will tell if that's a prudent move.

Leonard

Hybrids are fun, and push the envelope! My current fave set, the BGCD Regenerodyne, uses a 12A6-2N7000 mixer switched by a 2N3904 Pierce crystal oscillator, as well as a 2N7000-as-variable-shunt-resistor RF GAIN control.

As an initial guess as to why the source follower may improve selectivity, that may be because the higher input impedance of the source follower, in parallel with the 200-k plate load resistor of the 6AK5, make a significantly higher AF impedance at the plate of the 6AK5. That allows the 470-pF RF bypass C to roll off audio highs to a relatively greater degree.

I heard exactly this effect when experimenting with different detectors in the BGCD. With a 560-pF plate bypass C, I heard noticeably more high-end rolloff with a 12A8 pentagrid product detector (plate resistance on the order of 360 k) than with a 6GX6 dual-control pentode (plate R on the order of 140 k). The 12A6 Hartley is even better, for two reasons: its plate R is even lower (on the order of 70 k) _and_ its regeneration gives it significant selectivity of gain that non-regenerative circuits can't provide.

You should also be getting somewhat higher output from the 6AK5 from the same cause: A higher AF load Z for the detector should let it develop a somewhat higher maximum output voltage. Higher gain in the AF passband you want combined with relatively lower gain at the higher audio frequencies you don't want should result in quite an improved sound.

Best regards,

Dave

Thanks, Dave. I was sure the increased gain and selectivity was because of the higher impedance load on the detector. This configuration may show up in future projects.

Hello Bry,

You might try to be more precise, as there are two model "310" CROs from H.P.
One is a vintage analog animal, probably good to 10 MHz. The second is a digital beast, good to 50MHz.

The second sells from US$200 to $350.

Les

Could you provide a schematic of your 2n7000-as-variable-shunt-resistor RF gain control?

I am attempting to design a regenerative receiver that is purely controlled by voltages. I know how to control the regeneration via voltage (easiest way is to control the detector Vcc; another way is a varactor as a "throttle capacitor"), and how to control the tuning via voltage (use a varactor to tune the tank).

What I don't know how to do (easily) is make a linear, voltage-controlled RF attenuator. Altering bias of an RF preamp is out, as that will encourage IMD in the preamp at low gain levels. I sketched up an attenuator design using several PIN diodes, but that was too complex for my taste. I always thought there must be a good way to use a FET for this purpose but couldn't come up with a circuit that seemed plausible and had a wide dynamic range.

Because you mentioned "hybrids", you can probably guess at my ulterior motive for attempting to design a regenerative receiver that is purely controlled by voltages.

I should add that the most convenient way to implement this strategy is with a resistor from drain to gate, and an equal-value resistor from gate to the control voltage. This arrangement assumes that the source terminal is grounded, which then allows the control voltage to be ground-referenced, rather than floating (as would be implied by a literal translation of the description given earlier).

A couple of quick comments:

When you vary the supply voltage, you are also varying the current, so calling this a voltage control method is somewhat arbitrary (and may possibly obscure important dependencies).

That aside, the standard way to use a FET as a fairly linear voltage-controlled resistor is to add half of VDS to the control voltage, and apply that sum as VGS. The drain-source resistance will then remain approximately constant over a much greater VDS range than a standard triode-operated FET.

At low frequencies, you may derive the half-VDS voltage through a simple resistive divider across drain and source. At higher frequencies, you will need to drive the divider with a buffered version of the drain voltage (to allow use of lower-valued resistors, and thus smaller RC time constants formed with inevitable parasitics).

Tom

qrp.gaijin wrote:

> Could you provide a schematic of your 2n7000-as-variable-shunt-resistor RF gain control?

I'll get a schematic of my approach up on my site somewhere so I can link it in. It's pretty cheesy--basically just use the FET as a shunt R to common--but it works well enough for me.

MOSFET have sharp threshold knees, so linearization of the FET transfer characteristic really helps expand the resistance-v-control-rotation characteristic of the system. Tom has well described how to do this--it's _really_ simple, two resistors, one of which provides drain-to-gate feedback; so you can see a drawing soon, see Figure 6 in http://www.vishay.com/docs/70598/70598.pdf http://www.vishay.com/docs/70598/70598.pdf .

I first ran into this linearization technique in Horowitz and Hill's _The Art of Electronics_. I found another cool use for it: Implement a simple S-meter for a receiver (Yaesu FR-101S) with a positive AGC bus. Just linearize a 2N7000 and connect it across the meter as a shunt, using a dropping resistor from supply to the meter to set "max." Do a bit more fiddling to bias the FET threshold and control the FET bias from the AGC line, and then at AGC max the meter is maximally shunted, and as AGC voltage drops with rising signal voltage the meter is shunted less and indicates more. The result is a meter with a hot low end and a compressed strong-signal end. (I also designed and breadboarded a serious level-shifting, op-amp-summer-based equivalent that has zero and max set, linear range, blah blah blah, but the simple FET thang works so well [and I so consider S meters to be _so_ non-indicative of anything really important], that I keep not getting around to building the higher-tech version. _Radio_ is more fun.

And course feedback can help out with other MOSFET applications. It turns out that just a bit of _capacitive_ drain-to-gate feedback around a big, high-voltage power MOSFET makes it a peachy cathode keyer with nice smooth rise and fall edges. Because of the high transconductance of these parts, that's with just (for me, who likes things a little soft) 560 pF from drain to gate; with 0.001 uF or more and you can approach the bong of primary keying a la W2AN. A separate FET per keyed stage avoids common-impedance situations that may make for interstage-enhanced nonfun with various sorts of parasitic oscillations, including those made possible (in beam tubes) by screen and plate intrinsic negative resistance.

If you mean three pieces, i’d say except for the 6SK7 tube, it’s a copy of the Walter Ashe kits described in two 1950s RADIO NEWS magazine articles.

I have seen a whole lot of build – it articles and books, and i have never seen a single tube 6SK7 receiver used paired with a transmitter. 6SN7 yes.

So i’m wondering if the builder extemporized on his own here.

What is the size of the chassis? That may be a clue also, as the build articles specified the chassis size also.

6SK7.... very nice metal encased tube ... used by the PARASET
and many other nice designs...
Modified PARASET here used 6SK7 regenerative detector,
6SK7 (OR 6SJ7) AUDIO PREAMP AND 6V6 Audio power output...
Room filling volume ... nice AM broadcast band reception optimized
by feedback loop from 6V6 to 6SK7/6SJ7 audio preamp...
Could had been better optimized by adding a 6SK7 triode connected
as grounded grid RF amplifier stage...
Using now my favorite Soviet era 7 pin and 9 pin miniature tubes
this radio would be 6AK5/5654/6ZHE1P triode connected grounded
grid RF stage, another one as screen grid controlled regenerative
detector... another one as audio preamp... or a triode/tetrode
audio tube 6PHI5P... (beefed up ECL82/6BM8...
Run them with no more than 130/ max 150 volts... regulated at
105 or 75 for the detector stage... Go for 6.0 to 6.4 volts regulated
DC for the filaments and make the power supply pack built on
another chassis.. (makes a very useful workshop accessory too)
When builders follow my circuit design... I recommend to start by
winding the AM broadcast band coil... just to show how sensitive
this radio is... Daytime razor sharp adjacent channel separation
possible to pick up a 940 kHz station 220 miles away with the
presence of very well modulated 10 kW local on 950 kHz...
Bandspread coils for the ham bands... and using a second slow
motion 20 pF variable capacitor from defunct FM tuner makes this
design a very viable second ham station receiver for those who
already own a nice radio, and it does work quite well as a main
station receiver if you don't have a good radio already...
SSB , CW and digital modes reception is excellent... BUT remember
to build the regenerative detector stage like a good quality VFO
and use the best possible air spaced variable capacitor and
dial mechanism...
Just getting parts together here for assembling another one for
a disabled radio amateur... that I am sure she will enjoy using
it at her station...
BTW... absolutely NO critical parts ... many values can be below
or above recommended parts values and the radio will still work...
something important for those living in parts of the world that
can not access E ¨port¨ or buy from Internet sources...

73 and DX
Arnie Coro
CO2KK
Host of Dxers Unlimited
NOTE: 7 pins and 9 pins miniature tube sockets may prove

to be hard to find... but you can insert the tubes into little
holes on a printed circuit board, and solder directly to the
tube pins, because those tubes are very long lasting... HI HI

My guess on this one is 73 Magazine. PE is a good second guess.
I’m pretty much through with my magazine collection downsizing, so coming across these articles
again is less likely, but if i see them again, i'll note it. I donated many lbs. of magazines to
americanradiohistory.com and many to hamfests, and the local recycling center, but i tried to
log interesting articles as i did, but just not enough time to do a thorough job.

26363. 2.5v Filament Tubes

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-11 22:30:23 UTC
From: J Ed
Topic: 26363 Message: 26363

I'm looking to build a tube receiver and it will likely use low voltages for the plates. I'm deciding if I want to use miniature all glass tube or some of the older 2.5v filament tubes. I have four 27s, four 35/51s, a 24A, and two 47s (possibly working for a small transmitter?). The receiver would have to have four tubes with filaments in series.

It's possible a tube collector could want these tubes and would buy them from me. Then I would have my choice made for me. I have some 6EH7s that have tremendous gain. I'm also concerned that two 35 and two 27s would not have much gain unless I cranked the plate supply up to 45 volts or more. That's doable in the age of inexpensive boost converters.

Has anyone else used tubes like this to make a receiver? How did it compare to receivers made with more modern tubes? It's possible I could make a simple superheterodyne receiver for a single band (something like 80 or even 40m). I'd just have to be careful about the layout.

Uh...or by using a power transformer that puts out, say, 56 V. You can buy them for Digi-Key.

> Has anyone else used tubes like this to make a receiver? How did it compare to receivers made with
> more modern tubes?

George Grammer described in December 1930 QST a widely-duplicated a.c. operated regen that used a 24A detector followed by a 27 AF amplifier. In its writeup he mentioned that it really needed an AF GAIN control.

In September 1931 QST, James Millen described the design of the National SW-3 regen. It used a 35 as its detector.

We got to this point because those tubes worked so well in those applications then. They'll still work fine now.

Best regards,

Dave

Ed, I don't know if this will help, but My Mk.9 regen receiver used all 2.5V tubes. In my case I got a transformer from Radio Daze (I think) that had 2.5 and 5.0 volt windings. Four tubes are connected in parallel on the 2.5V winding and two are in series on the 5.0V winding. The set works well enough, but the old tubes tend to be a little microphonic. Also, I prefer high voltages and don't know how these tubes would work on low voltage.

I stumbled onto this vacuum tube experimenter board:

http://www.learnmorsecode.com/regen/exp/exp3.jpg

on
http://www.ak-modul-bus.de/cgi-bin/iboshop.cgi?showd930!0,719892259480343,KITRT100

under Dokumentation

found a PDF in English

http://www.ak-modul-bus.de/cat/documentation/RT100_en.pdf

that had great explanations of how to build tube circuits.

check out these 3 images:
the board:
http://www.learnmorsecode.com/regen/exp/exp3.jpg

a circuit:
http://www.learnmorsecode.com/regen/exp/exp1.jpg

How to wind the shortwave coil:
http://www.learnmorsecode.com/regen/exp/exp2.jpg

Can anyone recommend a tube based experimenter board like this one?
This is the first one I ever saw and the web site is in German so I'm not
understanding much there.

Hi Ed
You mention that you would have to use 4 tubes in series are you thinking that you can use a 6.3v filament transformer to power the heaters?? Remember that the current of each must be the same in order to do this. If you are going to use a 47 tube it is directly heated (no cathode) so the 2.5v filament winding must have a center tap in order to act as the cathode connection. If you are sold on using the 2.5v tubes a 2A5 is a good choice for the audio output.
In regards to using modern hi gain tubes generally speaking you don't need a lot of gain in the detector stage. You may find that it might be hard to tame. Audio gain is a good thing if you are driving a speaker, for fones don't need a bunch.
Not sure about using low voltage on the plates. On triode detectors I've used around 35-45v on the plate and wound the feedback winding accordingly. Dave mentioned the SW-3 it uses 35 tubes but runs about 200vdc on the plate and controls the regeneration with 20v (0-36vdc) on the screen grid.
Just a few thoughts
Terry N3GTE

I'm looking to build a tube receiver and it will likely use low voltages for the plates. I'm deciding if I want to use miniature all glass tube or some of the older 2.5v filament tubes. I have four 27s, four 35/51s, a 24A, and two 47s (possibly working for a small transmitter?). The receiver would have to have four tubes with filaments in series.

It's possible a tube collector could want these tubes and would buy them from me. Then I would have my choice made for me. I have some 6EH7s that have tremendous gain. I'm also concerned that two 35 and two 27s would not have much gain unless I cranked the plate supply up to 45 volts or more. That's doable in the age of inexpensive boost converters.

Has anyone else used tubes like this to make a receiver? How did it compare to receivers made with more modern tubes? It's possible I could make a simple superheterodyne receiver for a single band (something like 80 or even 40m). I'd just have to be careful about the layout.

I was looking at 56v transformers as suggested by another guy here. They are decent in price and I'd like to get one for a small receiver supply. Still, the 2.5v tube seem to be too much trouble and I think I'll sell the ones I have. The 56v transformer will give 80v and likely will do 95 to 100 if lightly loaded.

A 24A uses 1.75A for the heater, which is a tad over 4 watts. A 6AU6 uses 1.9 watts for the heater. This means I can get twice as many tubes on the same A supply. There are many transformers that do 12.6v center tapped. These transformers will be great for powering filaments. I am not sure what I want to do but I had IF amplification in mind.

My original thought was to run four of these tubes with their filaments in series (adding up to 10v) and placing in a small resistor made of Kanthal wire to use up the remaining volts. I've also thought of making a rheostat with said wire for making a twin plex receiver using a battery tube.

From: J Ed
Topic: 26369 Message: 26369

I've determined that the 2.5v tube will be a no go. I do want to try something else, though. I'd like to make a receiver that goes inside a wooden cabinet. That's nothing new, as receiver cabinets are commonly and easily made from wood. I'd like to make mine a cathedral cabinet shape, though.

To do this, I'll need to know how to bend plywood into the shape of an arch. I have seen methods that involve soaking the wood, steaming it, etc. I'd also like for my cabinet to have a vintage look, meaning I'd rather not use MDF or plastic. Still, I'm learning a new skill and have to be open to new ideas.

That's a good idea too. I can stand to do several layers. One thing that occurred to me would be to make a panel from 2x4s sliced to 1/4in or thinner on the table saw. I'll probably make a small cabinet to house a small speaker and then make a bigger one capable of housing a full radio. It might be a sin to place 60s tubes in a 30s cabinet. Oh well.

See? This is why I asked this group. I'm already getting lots of good ideas.

Don't need steam. You can use a "bending iron" which is basically a hot pipe. The hot pipe softens lignin in the wood and you can easily form it to the desired radius. This is how violins, guitars, and other stringed instruments are formed. Works fine with thin sections.

Bending ply (wacky wood) is sold in 1/8" and 3/8" thickness. The 3/8" is quite rough and the 1/8" is nice and smooth. Try finding a local cabinet shop to see if they have any cutoffs you have and could use. You will need to make a simple form to glue a couple of pieces together to form the shape you desire. That could be made out of that 2" "blue board" insulation from Home Depot.

Greetings Everyone
This may not be for everyone, but had this happen a
couple of times over the years. I stored wood from an
old piano and an old dresser in a tin shed for a few years,
and decided to clean this up and the veneer had separated
from most of the wood because of humidity and such. I
separated this and saved the veneer for future projects.
Did find a 'little' mold, but for the most part all was pretty good.
On another occasion brought home an old tube type stereo,
TV and radio and parted it out. Only about a week later went
to take the wood to the landfill and the plywood and veneers
were separating from that wood already. So, if you happen
upon an old dresser or something similar, just lay it on the sod
and it will collect moisture or spray it down a few times and that
glue might separate for you and you'll have free woods and
veneers to play with. I know that don't sound the best, but
it is a good way to recycle :)

From: Jim Pruitt
Topic: 26369 Message: 26383

Ed, if you have a hobby shop or maybe a Hobby Lobby/Michaelson type craft store they have aircraft plywood (usually distributed by Midwest Industries) in 1/64" up through 3/8" thick sheets up to about a foot wide and 4ft long (usually only up to a foot wide except some model airplane type hobby shops have longer and mail order like Midwest and Lone Star Balsa and many other online hobby distributors) the thin stuff I'd usually used for model airplane wing skins. Thicker is used for fuselages. I don't know what width and thickness you are looking for but the aircraft grade plywood up to about 3/32" bends fairly easily.

Hope this helps. Good luck.

Yeah, not strictly Regen related, but we ALL do use soldering irons of various types.

About a month or so ago I bought that 1000VA 'isolated' Variac (isolated because the primary is isolated from the secondary as in a standard Isolation Transformer.

Well, I didn't expect to get a LOT of use out of it as I only occasionally work on old tube stuff that would benefit the most. It was purchased as a "safety item" for the bench.

Well, yesterday I received a box containing a LOT of terminal strips with parts attached, potentiometers (sp?) and so forth. LOTS of cleaning up to do. I first started the task by using the soldering iron on my soldering station that has the larger tip (the station has two irons). It did the job, but took awhile to heat the terminal lugs and work the parts off. Most of them are those type used military type that have two rows of hollow posts on a phenolic or fiberglass plate with the parts between the two opposite posts. Takes more heat than the typical PC boards.

So then I switched to the smaller (100/140 Watt) Weller gun. IT too worked well but was a bit clumsy.

Then I thought of the 60W Sears Iron. The one I usually reserve for PL-259 plugs. Gets very hot and transfers a LOT of heat. A little too much sometimes ;-)

Then I saw the Variac sitting there. Set it for about 95V, plugged the iron in, and Voila! Instant variable temperature soldering iron. It looks like it will be ideal for the task at hand, and no wear on the soldering station irons or soldering guns (yeah, I probably went overboard on setting up the soldering capabilities of my bench (grin). That Sears iron has been sitting in the toolbox for years with only occasional use. But at least I DO know which end of the soldering iron to hold on to. . .

One thing about the Weller guns; the trigger switch contacts will weld if
you keep it on too long, like when you're stripping circuit boards. I ruined
a few of my guns that way.

lots of steam with the plywood mounted in a jig to help bend and hold shape while the moisture evaporates.
73,
kevin
kc6pob

I've determined that the 2.5v
tube will be a no go. I do want to try something else,
though. I'd like to make a receiver that goes inside a
wooden cabinet. That's nothing new, as receiver cabinets
are commonly and easily made from wood. I'd like to make
mine a cathedral cabinet shape, though.
To do this, I'll need to know how to bend
plywood into the shape of an arch. I have seen methods that
involve soaking the wood, steaming it, etc. I'd also
like for my cabinet to have a vintage look, meaning I'd
rather not use MDF or plastic. Still, I'm learning a new
skill and have to be open to new ideas.

Hi Leonard,

I use a propane torch for that! Get lots of parts in a short time. Melt
the solder in a large area and tap the board to make the parts fall off.

I've done that, Bill, but not when I wanted to reuse the board. For that my trusty soldering iron does the job.

I'm more of a "purist" and would rather use a real wooden breadboard/cutting board to mount the components. Newer, plastic boards work as well. Just mount a protoboard strip and tube sockets. The protoboard can be any size, not just the one shown in the pictures. If using higher voltage tubes (versus teh 12 volt versions used), one must keep in mind the interface parameters to modern electronics, especially when dealing with microcontrollers and TTL and CMOS type logic which are current and (positive) voltage limited..

By making your own board, you are not bound to just using low voltage tubes.

My interest level in the German proto board was because they have a user guide that explains in detail how
to experiment with tube circuits.
Upon further poking around the web I found there was a real book ... not just a user guide ....that had experiments to do
on the German proto board.
But that book is only in German so I'm not going down that path.

I makes more sense to build this proto board you found.
I can do that.

As far as voltages goes.....

My very first HF radio here was a $10 kit.... KNIGHTSMITE.... 3.686 Mhz CW transceiver.
It fit in a mint can with its power supply... a 9 volt battery.
I built one and my 12 year old son built one.
Mine worked fine but
when my son pressed the straight key to transmit Morse code we had a very interesting event.
His circuit board smoked.
His inductors smoked.
The vinyl table cloth melted in a 6 inch ring around his KNIGHTSMITE and then ignited
while the wooden table blackened.... real fast ... as fast as you could key dit dah dah.
Just at that moment my wife walked into the kitchen watching us burn the kitchen table.
Of course the reaction my son and I had was nothing less than us bursting into laughter.
Of all the possible things that could go wrong, fire was not even a considered option when
building a 9 volt powered circuit board the size of a postage stamp that expected to yield
about 300 milliwatts of output.

So if 9 volts will burn the table... gee... I wonder what 350 volts will do?

26396. bread board plastic cutting board

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-14 07:17:16 UTC
From: Rob
Topic: 26366 Message: 26396

Is there any way to actually identify what kind of plastic a cutting
board in made out of?
I bought 3 different cutting boards.
Each is a different thickness.... 1/8... 1/4... 1/2 inch.
Each has different cutting properties.
The 1/8 and 1/4 melt and bubble a jagged edge when cut with a circular
saw or drill.

The 1/2 inch cutting board cuts clean like MDF Medium-density
fibreboard
and drills clean
AND
can be tapped with threads.
All sorts of radio parts can be made with this stuff.
I just haven't figured out what temperature it would fail at yet.

Rob wrote:

> So if 9 volts will burn the table... gee... I wonder what 350 volts will do?

Could be interesting, if, as will your tablecloth-melting experience, you don't carefully check wiring and check for solder bridges.

But there's another aspect. The power supply was 9 volts -- got it. But what kind of battery? I'd be amazed if the short-circuit current in a 9-volt transistor-radio battery could source the sort of current that would make inductors, resistors, and your tablecloth smoke. Bet you were using something with considerably higher current capability than a 9-volt "transistor radio" battery, which inside is really just 6 wimpy little 1.5-V LeClanche cells in series.

Few tube users will be sourcing the likes of 350 V from a battery; most will use transformer-rectifier-filter power supplies. Although it's possible to build a herking high-voltage supply such that short circuiting it through the gear powered melts things and keeps melting them, that wouldn't go on for long. Resistors smoke, of course; transformers have a special way of complaining... Maybe one's power-supply diodes don't go (if they're solid-state) before something else opens up; vacuum-tube rectifier plates, on the other hand, immediately overheat to bright orange. High-voltage shorts from line-operated supplies tend to cause bangs and not just smoke because the energy stored in filter capacitors is suddenly discharged.

So it pays to keep the current capability of the power source in mind when experimenting, either using current limiting, perhaps a fuse, at first-power-up time.

By the way, in the area of battery source current, a _QST_ author I worked with was in aerospace and did an article for us about managing nickel-cadmium cells/batteries for long life. Compared to carbon-zinc cells and even lead-acid car/boat/golf-cart cells, an equivalent NiCd cell can source astoundingly high current, such that they're used to help start jet engines, which starting sequence goes on for much longer, and requires much more current, than any equivalent automotive process. (I see that for this same reason, NiCds are also the thing for starting one's helicopter.) So batteries for that service are quite robust, and last a long time. The short story is that he was able to score himself an NiCd starting battery--a preventive-maintenance pull--for his car. You know how we end up replacing our lead-acid car batteries multiple times over the lifetime of a vehicle? He was able to use the same "used" NiCd starting battery _across the lifetimes of three cars_ .

Best regards,

Dave

Not sure of the plastic material which can be different from store to store. I get mine from the Japanese markets or the Japanese version of the dollar store - Daiso. I have noticed that the thinner boards do have a tendency to warp so i would go with the 1/2". I would also consider mounting the sockets on standoffs to allow access to the pins below as well as a bit of air. The glow in the tubes (heaters) could affect the plastic below (refer back to first sentence).
My preference is a wooden cutting board (finished or unfinished) for that classic look! I just found an old turkey carving board in my garage which I am considering refinishing and salvaging for a project.

One of my first electronics projects was a magnetic pulse generator designed to make a changing magnetic field for arthritis. I don't believe it would actually do that but I wanted the experience.

I wired the 555 timer circuit wrong and it latched the TIP31 output transistor on. That caused the metal tab to heat up enough to melt solder. The supply was a 9v battery. I still keep that transistor, somewhere.

Hi,

I have read accounts of a single, 9-volt 'transistor' battery causing burns that needed treatment when carried in a pocketful of change. Treat them with respect. After I read about that I stopped doing the 'tip of the tongue' test. When they test good we are experiencing the beginnings of burn.

RE: Bet you were using something with considerably higher current
capability than a 9-volt "transistor radio" battery, which inside is
really just 6 wimpy little 1.5-V LeClanche cells in series.

NOPE... nothing more than a DURACELL coppertop plugged into the KNIGHTSMITE
made of these parts:
http://www.qsl.net/kl7aqc/frklsmpcbH.html
http://www.qsl.net/kl7aqc/frklsmppch.html
http://www.al7fs.us/SmiteAltoids.jpg

http://www.qsl.net/bd6cr/pixie/Pixie_improvement.pdf

And about pocket fire.....
I had a SANSA CLIP mp3 player the size of a large postage stamp that
became a pocket toaster roasting
chestnuts.
That was a USB rechargeable battery. Don't know the chemistry.

I have wooden base tube holders that I can mount on plastic board
without melting.

Almost certainly a Lithium battery, of which even small ones can source
heavy currents, and in some cases even cause a fire or explosion (though
usually safe in a device like a MP3 player etc).

I have a little cordless soldering pencil that just uses a couple of
penlight cells, and it surely melts solder.

Hi,
I don't know about 9V batteries but a 1.2V Nicad can ruin your day. I used to light my model airplane engine glow plugs with one. I bent a small U shape on the end of a wire then taped the wire to the side of a cell. I would hook the wire (-) over the plug and let the plus bump touch the cylinder. Worked great for starting. One day I started the engine and dropped the cell into my pocket. It shorted out on a coin in my pocket and gave me a bad burn on my upper thigh. This in spite of shucking myself out of my pants in about two milliseconds. I bet my club members still laugh about it.

You are absolutely right about this. I did a ‘dead short’ test on this size battery a few years back, and while i don’t remember the exact number of amperes

they will drive, they definitely can drive amps to heat up or melt metal. This is a “single use” stunt; the battery doesn’t recover from this.

And yes, i have seen techs “test” batteries for “freshness” by the method you refer to, but it always looked kind of disgusting to me.

I play musical instruments that require 9 volt batteries.
DURACELL COPPERTOP 9 volt batteries cost $5.
My gear requires 4 batteries.
If something does not work then the battery is ALWAYS the suspect fail in the chain of technology.
If I pull apart a device and put down a battery , or two, I always rely on tasting the battery to know which one works.

I have extremely low amperage amplifiers that take a month or two to kill a battery
and
I have a reverb pedal that sucks down 100 milliamps and will completely stop working because it draws a
carbon 9 volt battery down below 8 volts in LESS THAN THE TIME IT TAKES TO PLAY THREE SONGS.
AND
will stop working in less than an hour on a DURACELL COPPERTOP battery
so I have resorted to PAIRING two 9 volt batteries together in parallel to share the burden
and those TWO batteries will last a month under that load stress.
So just for giggles.....
I sewed together FIVE 9 volt battery clips to one plug and used the El Cheapo
ONE DOLLAR batteries and got weeks instead of minutes out of them.

And probably licked every one of them a few times.

The 9 volt batteries were never designed to source 100 mA. They were intended for a max draw of around 10-15 mA max and maybe occasionally peaking 20 mA.
Even 20 mA is a damaging load to them. The problem with the "taste test" i think, is that it does not test the battery under a realistic load. Battery test devices
DO include a resistance load.
Many instruments now do include built-in preamps or tuning devices. The only caution i find about what brand battery to use, is -- the battery to use is the one
you will check up on regularly. Leaking batteries are potentially deadly to electronics and positively destructive to resale value.

There is a brand of battery - Duracell "Copper Top", which in the 1.5 volt size, in AA and maybe others - that has a built-on the cell case - battery tester, which
has a row of colors red, yellow, green, to show the cell state. I carefully pealed the test strip off the cell using a sharp box knife. This is crude surgery and the
survival rate of the patients is not high. I was thinking i could use the strip for a transmitter RF output indicator or for a front panel battery indicator. I found
the resistance of the thing around 5 ohms, so it's throwing about a 300 mA load on the battery for a test, which seems like a good rigorous test for an AA.
I did get a couple of the strips off and still working, but the resistance is too low for an RF transmitter load, by itself, and besides, the strips are VERY fragile
when they're off the battery, so i pretty much gave up that experiment. It was fun, though, doing.

One of the weaknesses of batteries is the battery contacts.

Which reminds me. The 45 volt batteries we used in the landline telephone industry would drive up to a couple amps. The reason i know this is, there was a device called a "burn box" which used a stack of them to deliver around 500 volts for diagnostic testing. The self-test function of the box called the batteries good if they would deliver at least 1.5 amps direct short - internal resistance being the limiting factor. Of course 1.5 amp is a lot more than we require for radio use, so i always tried to scrounge the old batteries when they were changed out, twelve or 16 of them in a box. The old discards were fine for battery-tube circuits and i gave boxes of them to a friend to power his GRC-9 receiver and the Chinese 103E clone of the GRC-9. Wish i still had a steady supply of them but that's over. The current "burn box" uses a rechargeable Nicad battery and a step-up circuit; the old 45 volt batts were just too expensive to replace - as you all know. I still have a few boxes of those batteries with date codes back to maybe 10, 15 years ago and those used batteries will still power tube circuits. These late-model 45 volt batteries actually used 30 AAA cells soldered in series. The "burn box" was used to find a resistance leakage spot in cable pairs; the high voltage would break down the leakage and fuse the wires, so that a fault distance locating instrument could more easily find the defect location. (I heard one story of some techs on a trouble call, discovered that the complainant's lowlife neighbor had tapped into his phone drop (wired service) to get free phone service. The tech isolated the wires to the suspect's house, and applied the burn box to the line. That ended the usability of the suspect's phone. I don't know the veracity of this story.)

Some few, a small minority of 9 volt batteries use 6 AAAA cells in series inside, friction fit, not soldered, instead of the sandwich-cell construction. I have ripped open those 9 volt batts to harvest AAAA cells for special project use where i specifically wanted that very slender cell size. (Specifically, to make a 'bias battery' with three of these, for the GRC-9 receiver, which uses a 3Q4 output tube.) ** I have not actually seen any equipment that uses AAAA cells but you can buy them, just not at any store near you.
-Hue Miller

**The unexpected finding on the GRC-9 receiver is that using a "bias battery" for grid1 is that resting plate current is insignificantly different whether you use a -4.5 bias or zero bias. I'm sure this is not the case for output triodes or tetrodes or larger pentodes. The only observed difference is that 3Q4 with zero bias, strong audio played at loudspeaker level, shows distortion.

I stand corrected about their short-circuit capacity. I commonly don't use 9-V cells (unless equipment calls for them) because they're so expensive for the capacity you get. Line-operated power supplies with short-circuit shutdown give a false sense of security. My big ICOM 30-A supply, with a power switch and terminal posts added so it can be used as a bench supply, is so finicky about low-Z loads that it won't start up properly just two or three 12.6-V tube heaters preconnected at power-up. (As is true of all metals used at incandescence, their resistance is much lower cold than hot, so to use that supply to light tubes I disconnect the tube-heater load with the supply turned off, power up, and then reconnect the load.)

And BTW, not to re-open the discussion of transformerless power supplies, but another positive of having transformer between the equipment and ac line, even a 1:1 (isolation) job, is that it serves as a current limiter in the event of a short circuit on the secondary side. Plenty of bad stuff can still happen with a hard, long-term short on the secondary side--including the death of the transformer--but at least the full capacity of that branch of the line (otherwise limited only by a fuse or breaker at the electric panel, maybe backed up by the breaker on the outlet strip one may be using) isn't available for mischief.

My first and last experiment with a transformerless supply--had plenty of event-free All American Five experience with them, but those were factory-built jobs--was at age 15 or 16 with a half-wave-rectified supply for a portable Boosted Pierce tube transmitter. I thought I'd installed sufficient current-limiting resistance in series with the (black painted glass) rectifier diode, but after the loud hum and pop on power up the diode's two pigtails were just pointing at each across space with no diode in between.

Best regards,

Dave

Sounds like the thin boards were polycarbonate or polypropylene. Was the plastic stiff and brittle (PC) or bendy (PP)?

You can sometimes identify a plastic by its resin identifer. That's a number inside a triangle of arrows (recycle symbol). Not all plastic objects have it.

The thicker board sounds like high density polyethylene. Works well for RF as long as you don't try to solder anything that's in or on it.

Dave Schmarder's tube radios are almost all built on a deck of HDPE over oak. I think he orders it in sheets, though.

Complete top deck made of plastic........
I had not thought of that at all.
I am using the 1/2 inch thick cutting board plastic as the end pieces to make butterfly
air tuning capacitors and filament rheostats fashioned after the cap ceramic end plates
and fiberboard and phenolic flat parts in rheostats.

I unpeeled the casing from some dead batteries and found that,
in some cases, it was just the internal contacts that had
corroded. Without top (or tail), they were still good for quite
some time - but needed monitoring :-)

I use a flashlight bulb for a rough check.

When batteries still contained mercury, licking was probably
even less of a good idea. What some from exotic parts might contain,
I know not.

Thanks for the Fifths Circle, Rob. Wish I had had that when
I learned to play the piano at school!

Hi Dave,

"So expensive" or not is subjective. I agree they are not the cheapest source of energy. In some of my applications I find them reasonable. In those applications I don't use the 9-volt batteries that cost five bucks each. The ones I buy are alkaline batteries at just over one dollar each. I use them in series stacks to give me 45 or 90 volts. The most used application here is operating vacuum tube receivers (B+) and the bulk of that has been the six-tube "ARC-5" command receiver superhets. At 90 volts those draw about 16 milliamps from the B+ line. At 45 volts I measure one half of that at about 8 milliamps. The batteries last several weeks (months) at an hour or two per night. The heaters are operated from 12 volts sealed lead-acid rechargeable batteries. Except for the "battery tubes" the heaters are the real hungry parts. There is no way to make tubes as efficient as transistors. But they are fun to play with.

When the electric utility drops the load (happens in batches of 3 to 8 days out here) the batteries don't notice. When there is crud (awful noises) on the power lines the batteries eliminate one means of injecting that noise into the receiver. The voltage does not wander up and down as the local load on the power lines do so one source of drift is eliminated. I can operate those radios at the park on a picnic table without an extension cord. I initially tried this out with the power outages in mind to see just how 'bad' those batteries would be. I was surprised to find them not so bad after all. And especially when I observed the benefits.

Some hams use them to power vacuum tube QRP transmitters and similar loads are placed on the batteries. I am going to visit that use, too. There are rechargeable "9-volt" batteries (actually about 8 volts) and those might be more reasonable as to expense. My experience with rechargeable batteries is they don't last as long per charge as the alkaline batteries but can be recharged many times. Lithium technology might give even better results. At this time I don't trust those.

73,

Bill KU8H

26415. Looking for Testing Tips and Tricks (T^3)

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-15 14:48:05 UTC
From: Suzie Creamcheeze
Topic: 26415 Message: 26415

Greetings and Salutations Dear Friends,

I hope I can phrase this question in a way that will encourage a high signal to noise reply, or replies. ;)

I am a beginning Electronics Hobbyist, interested in learning more about Hobby Electronics by building radios. I do not have a STEM background. I can read and follow directions. Currently, I have a MASTECH MS8264 Digital Multi-Meter, a Siglent SDS1052DL Digital Storage Oscilloscope (50 MHz with Frequency Counter), and a soldering iron. The DSO is relatively new, and I do not know much about how to use it, yet. Any answers that discuss using a DSO would have to include where and how to hook-up the probes, as well as what settings to use. I am willing to build simple test equipment, if necessary. I would prefer to build than purchase because I always learn something new when I build it.

So far, I have built a simple Oatmeal Box Crystal Radio which receives local AM radio broadcast stations attached to a 35 foot random wire antenna and grounded to the copper cold water pipes; as well as "A Simple Regen Radio For Beginners" by Charles Kitchin, which has a 39 inch wire antenna and was built using Manhattan Style Construction. The Crystal Radio is powered by the RF from the antenna, and the Regen Radio is powered by a 9V battery.

I am currently working on a radio kit. The Assembly Instructions recommend building the kit in stages, and testing each stage "function" before starting the next function. However, the instructions do not include any mention of "how" to test each stage function, or what to look for during the test.

So the question I want to ask has to do with HOW to test a stage "function" before proceeding to the next function. The schematic of this radio includes various voltage reference points throughout the stages of the radio, much in the same way that the schematic of the Regen Radio had similar voltage reference points.

It is recommended to begin the build with the Audio Amplifier. I have seen this recommended in other radio builds as well. Evidently, the hum/buzz of an audio signal can be used as a test reference during subsequent stage construction.

Some things seem obvious, for example, to get an Audio Amplifier to work, the Power Supply (battery box, batteries, voltage regulator, and forth) would also have to be temporarily attached to the circuit, even though that step might be the last item in the instructions, when it would be permanently installed.

My question is NOT about how to test each radio stage "function" for this specific radio kit, but rather HOW to test radio stage "functions" for ANY type of radio build, Kit or Scratch-built. For example, "Build the Audio Amplifier first, and use it to test each subsequent stage, by .... (doing this, or this) attaching your DMM to this or that, and looking for .... (this or this), whatever.

I am looking for actual Testing Tips and Tricks that you use when you build a radio, preferably geared towards a beginner who is interested in learning electronics, but doesn't have a STEM background, and is not an Electronics Engineer, but a Hobbyist. Links to relevant web pages or books would also be appreciated. I have access to my local Public Library, and it has an Inter-Library Loan system, which I have used successfully in the past.

I have a few old (1990's) Electronics textbooks on my bookshelf, found at the local used-book emporium for a few dollars, and they cover basic analog electronics. I also recently purchased Experimental Methods in Radio Frequency Design, so I have it, as well, though I must admit, I have not had a chance to thoroughly read it, yet. (There is a schematic for a Regen Radio in it.)

Summary: How do you test each stage "function" of a radio build, as you build the radio, before you build the next stage? (Looking for Testing Tips and Tricks.)

Thanks in advance for your Testing Tips and Tricks (T^3).

An RF probe would help. Most everything in a receiver amplifies. You can use it to detect RF signal passing through the various stages. You just need a germanium diode, a 0.01 uF capacitor, and a 1M resistor.

It's convenient because you can use it with any DMM you may have.

Hello Suzie,
First, the best two test instruments you have are two eyes properly connected to your brain.

Next, you need a circuit diagram of the item you are testing/fixing.

You need an intuitive understanding of the signal level at each stage of the set - for example 10 microvolts at the aerial, 1 to 400mV in the stages before the detector, 1/2 volt to several volts in the audio stages.

Once you know this, you can select the best instrument to find the fault.
In the front end of the receiver, the signal will be so small you can't measure it - so in this case you must inject a signal and listen for it in the speaker. You can use a good quality signal source (RF oscillator) or you can use a square wave generator built from 2 transistors and a battery.

Experienced troubleshooters begin by injecting a signal into the "middle" of the signal chain. If the set is working AFTER that point you'll hear this in the speaker. In that case you inject a signal into the set 1/4 of the way from the aerial. If the set has a fault AFTER the point where you inject the signal you'll hear nothing. In that case inject a signal into the set 3/4 of the way back from the aerial.

I think you get the idea.

Many thanks Les,

Useful information. Yes, the first oscilloscope was sold and the second HP310 I have is a classy
older analog scope. Portable in size which is a plus.

I do have pictures available if you or anyone else would like to see it. I believe it is going to sell for
around $50.00 to some lucky person!

Hello Bry,

You might try to be more precise, as there are two model "310" CROs from H.P.
One is a vintage analog animal, probably good to 10 MHz. The second is a digital beast, good to 50MHz.

The second sells from US$200 to $350.

I have just added a pdf file to the files section, it's called Toko 10K Plugin Coils.pdf

It shows you how to make your own plugin coils.

For anyone that doesn't know...

Toko stopped making the 10K series of coils and they will soon be like Denco coils, impossible to get. There are still some around at present. The High Frequency coils you might be interested in are:

160 meters 1.8 Mhz BKANK3333R (1.8 Mhz)
80 meters 3.5 Mhz BKANK3334R (3.5-15 Mhz)
40 meters 7.0 Mhz BKANK3334R (3.5-15 Mhz)
20 meters 14 Mhz BKXNK3335R (10-22 Mhz)

Having plugin coils allows you to use the same coils across many different projects.

If anyone needs help on an easy way to make the pcb's, I'll post some information on that too.

John

There are two Peter Parkers. One has superhuman strength, saves the day, and is generally a legendary figure. The other one is a comic book character.

26431. 'Novice Pair' surfaces

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-19 19:40:58 UTC
From: Hubert Miller
Topic: 26431 Message: 26431

I recently bought an example of the QST 'Novice Pair', so after half a century of thinking about that project, i don't have to actually do the metal

work that so daunted me ages ago. The pair look pretty well built, neatly done, except for a couple "oopsies". The receiver has two knobs flanking

the central vernier drive tuning, but somehow the builder couldn't get the two flanking knobs at the same level, even though one is a pot, so has

freedom to be placed anywhere. The detector tube has a ceramic tube socket, while the audio tube is the common bakelite or whatever that

material is, in the wafer-type sockets. I only got one coil, so i'll be among those looking for 20 MEL and 10 MEL B&W coils.

The transmitter i noticed, the wooden dowel that supports the output coil is not varnished or otherwise treated. The dowel is of narrower

diameter than the coil, and i noted that what looks like lollipop sticks inserted between coil and dowel to hold the coil in place. That will have

to done better. Also the miniductor type coil, the plastic support strips have pretty much disintegrated. I have seen this before. I don't know if

that's a reaction to specific climate conditions or if it invariably occurs over time. I did not get any kind of power supply with the two, so that

will become my part of the Novice Pair project.

Oh yeah - i noted that the front panels are attached by those hex-head sheet metal screws seen on the back of older TVs and other such electronics. Definitely not a good touch, looks cheezy, and that can do with an improvement too.

Photos will be done - eventually.

Probably not very many of these were actually built, i suppose, altho everyone seems to have read about them.

There's the original, of course; this pair here; and another shown on the Glowbugs googlegroup recently, at least.

-Hue Miller

26436. is it OK to use two 12 volt transformers to make 170 volts

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-20 18:25:55 UTC
From: Rob
Topic: 26436 Message: 26436

Is it OK to use two 12 volt transformers to make 170 volts as shown in
this circuit?

12AV6 Vacuum Tube Radio shown here
http://www.bristolwatch.com/radio/index.htm

that uses a power supply built with TWO 12 volt transformers
that normally get used to step down 110 mains socket voltage to 12 volts.
++
http://www.bristolwatch.com/radio/tube_ps.gif
Pins 3 and 4 on the tube are the filament and require 12.6 volts AC or
DC. The power supply for the plate can be 150 to 170 volts. (This is a
seven pin vacuum tube.) The circuit above uses two 120 to 12.6 volt step
down transformers. By connecting the two transformers "back to back"
this serves to isolate the project from the power line to prevent
electric shock or having a "HOT" ground.
++

I have not seen this done like this before.
Is there any reason..electronically .... to NOT do this ?

Also..... the diode specified is a 1N4001.
I have 1N4003 and 1N4007 diodes..... is it OK to replace that 1N4001
diode with a 1N4003 or 1N4007 diode?

This works fine for low power or experimentation. I have a 220v to 110v transformer that I'm going to use backward to make a roughly 300v supply. It's a 300 VA transformer and I imagine I'll get more than enough power for anything.

A single 12AV6 is going to draw so little current that a pile of 9v batteries would last for a while. Still, if you want to use the back to back transformer method, you'll be pleased.

Ed AE7TE

Yes to both questions. It'll work fine.

The pile of 9 volt batteries solution has been my sole TUBE operating B+ power source
for the last year of fooling around with tubes. Seems that FIVE 9 volt batteries is pretty safe to play with.
TEN in series fires my spark gap transmitter. Always a hit with the kiddies. Something about fire.

I'm more of the transistor baby generation dabbling with 9 volt batteries regulated by 5 volt regulators to
power transistor circuits and PIC microcontrollers.
I have collected a few transformers to delve into learning tube circuits but I have not hooked anything to mains power yet....mostly because I want to live a little bit longer. I have vision problems so I was trying to learn how to play
with bigger radio components instead of crumbs like SMD.... but bigger usually means killer voltages instead of
battery power.

One of my transformers weighs 40 pounds.

I was mostly wondering if brand new transformers easily obtained... such as these 12 volt transformers...
would do the trick instead of relying on specialty transformers.
Its a question of repeatability. If I do build a radio and my radio club guys get interested in doing it
I didn't want to say its a "one off" because you can't just walk into the hardware store and get the parts.

Yeah.

You can place two 16v, 10va doorbell transformers, or any other pair of transformers, back to back and get roughly 180v. Just remember that if you use capacitors, place a resistor across them so the charge bleeds off once you turn power off.

The first time I did this was with two 12v, 1a transformers. As long as you're not trying to get more than 50 ma or so, you're going to be fine. You can also use 12v from the center of the transformers to heat the tube.

If you want to make measurements, use alligator clips and don't touch anything until the power is off.

DOORBELL transformers.....YES..... thats what I wanted to hear!

As I delve into the exotic world of NEW OLD STOCK and find that YES I
can buy
brand new tubes from Russia for $2 .... and its easy enough to blow $10 on
5 tubes... and have spares to boot......
I don't have that kind of luck with transformer pricing.
Seems transformers hold their value and cost more than I want to spend
to stock up on any kind of pile of them
to share with fellow hams experimenting.

But to find on EBAY

110VAC Power Supply Transformer 12V*2 DOUB 12VAC 5W

for $13 isn't so cost prohibitive to sew together TWO of them back to back

and still end up spending less than half as much as the

https://www.tubesandmore.com prices for transformers.

I just can tell a new ham that he has to spend $60 to build a power
supply for an experimental radio.

About that bleeder resister advice....

when you say place....
do you mean permanently solder into the circuit?
Or did you mean short the capacitors with a resister to discharge it
instead of getting surprised or killed by it?
What value resister?

Alright...

I'd advise you to make an audio amplifier in your power supply. If you're going to make numerous radio circuits, that is something you'll want to build once and not for every radio. You will need a transformer for audio output, which can be scavenged from a dead tube radio. If nothing else, look for a 70v, 10w speaker transformer. Although they aren't great for audio, they are cheap and will do well for a watt of audio power. The tube can be a 12V6, 12A6, or another power output tube. There are plenty of 12v filament tubes that can serve as output amplifiers. Bias the plate current to 15-20 mA. The amplifier can be in the same chassis as the power supply. This will make experimenting easy.

I'd look for something more robust than a 5w transformer. You could probably get a 12 to 20 watt transformer for about 15 dollars.

The bleeder resistor is a part of every power supply and serves to drain the capacitors when you turn off power. They are permanently soldered across the capacitors. For a 180v supply, a 100k resistor would make a steady current of around 2 mA, which always flows. If you have a 47uF filter capacitor, the charge bleeds off in 20s. If the capacitor is 100uF the charge drains in 40s. You don't want the current to be so high that it takes up most of the power supply's energy. Use two 220k, 1/2w resistors in parallel.

You could also put a 1/4w 10 ohm resistor in series with the output. Under normal current (20 to 50 mA), the voltage and power lost in this resistor is minimal. If a fault occurs in your radio, the resistor will see a much higher current and burn out. That will save your rectifier and transformer from excessive current. Consider it a cheap, low current fuse.

re:
I'd advise you to make an audio amplifier in your power supply.

That is a very good idea.
I may get to do that.

Many years ago I started looking into tube technology and was really lost.
I just never could spend the study time to pursue understanding it.
But I did collect the hard to find parts.... power and audio
output..Thordarson? transformers.
AND
a varying mix of tubes.

So I actually could , now, without resorting to using doorbell
transformers....
I could do what you suggested and build a new old stock power supply and
audio amplifier to
use in all future experiments.

I was contemplating the door bell transformer idea just to show newbies
it could be done.

Thanks for the detailed advice. I do need it.

As far as the idea of getting anything from a dead tube radio goes....
a bunch of guys recommended re-purposing parts .....variable air
caps... from old radios
BUT
WHERE do you get dead tube radios?
Dead tube radios are not very much available where I live.

Tube circuits are much simpler than transistors. If you want to get started
then you definitely should start with a simple power supply like this and
then you can trade up later.

> So I actually could , now, without resorting to using doorbell
transformers....

You can do it any way you want. There's nothing magical about a transformer
from, say, Hammond. Also, look at Antek toroidal transformers. They offer a
pretty good power for cost.

> I was contemplating the door bell transformer idea just to show newbies
it could be done.

Not a bad idea. It was the way I started.

> Thanks for the detailed advice. I do need it.

There's plenty where that came from.

Hard to say. They tend to show up in the oddest places. Other hams might have the parts you need. I am getting a massive choke for the cost of shipping from another mentor. You just have to keep looking.

>> Alright...
>>
>> I'd advise you to make an audio amplifier in your power supply. If you're going to make numerous radio circuits, that is something you'll want to build once and not for every radio. You will need a transformer for audio output, which can be scavenged from a dead tube radio. If nothing else, look for a 70v, 10w speaker transformer. Although they aren't great for audio, they are cheap and will do well for a watt of audio power. The tube can be a 12V6, 12A6, or another power output tube. There are plenty of 12v filament tubes that can serve as output amplifiers. Bias the plate current to 15-20 mA. The amplifier can be in the same chassis as the power supply. This will make experimenting easy.
>>
>> I'd look for something more robust than a 5w transformer. You could probably get a 12 to 20 watt transformer for about 15 dollars.
>>
>> The bleeder resistor is a part of every power supply and serves to drain the capacitors when you turn off power. They are permanently soldered across the capacitors. For a 180v supply, a 100k resistor would make a steady current of around 2 mA, which always flows. If you have a 47uF filter capacitor, the charge bleeds off in 20s. If the capacitor is 100uF the charge drains in 40s. You don't want the current to be so high that it takes up most of the power supply's energy. Use two 220k, 1/2w resistors in parallel.
>>
>> You could also put a 1/4w 10 ohm resistor in series with the output. Under normal current (20 to 50 mA), the voltage and power lost in this resistor is minimal. If a fault occurs in your radio, the resistor will see a much higher current and burn out. That will save your rectifier and transformer from excessive current. Consider it a cheap, low current fuse.

>
------snip---

I find them at garage and rummage sales held on peoples' front lawns or in their um..garages. I get them for a dollar or less. If they are in good condition and the sellers can deomnstrate that they work (antique collector items) they want more money. Those are not the dead junk we are talking about..pass them by. We really don't want to wreck working radios.

Don't overlook the AM-FM-(possibly short wave) radios. They have more RF parts in them. Most of them have isolation transformers in the power supplies. Another good choice is the vacuum tube home entertainment units with turntables and often AM-FM tuners in them. Again - non working units go cheaply.

I have purchased a few *loaded* units at the "thrift stores" for a few dollars more. If you are interested is such things you can harvest some nice wood from those and not just the electronics.

This list is all about receivers - regens in particular - but receivers are used with transmitters by some of us. Most of what applies to regens and other receivers applies to transmitters as well. It is completely reasonable to build a low power transmitter around "receiving" tubes - up to around ten watts with modest B+ voltages.

The doorbell or control transformers can be abused back to back as already described. You may also use them singly in a voltage multiplying power supply to get somewhere north of 100 volts from the 12 or 24 VAC they produce. I now prefer to follow the AC power supply with a solid state regulator (high voltage transistors) to give the plate circuits 45 to 90 volts of very clean DC. Like a series stack of 9-volt batteries on steroids. And I still use the stack of 9-volt batteries.

73,

Bill KU8H

Permanently solder into the circuit, across the output terminals of the supply.

We call such a resistance a _bleeder_ because its purpose is to "bleed off the charge" of the power supply filter capacitors when you turn off the ac power to the supply.

Two 100,000-ohm, 1/2-watt resistors connected in parallel (or three 150,000-ohm, 1/2-watt resistors connected in parallel) will do it. This will give you a 50,000-ohm, 1-W resistor (with the 100k jobs) or a 50,000-ohm, 1.5-W resistor (with the trio of 150k parts). Assuming an output of 180 V (that would only be with next to no load on the supply, but we'll use that value because it's worst-case from the standpoint of power dissipation in the bleeder resistance), a 50,000-ohm resistor will dissipate 0.648 W. (Voltage squared divided by resistance.) Using a resistance that can safely dissipate 1 W or 1.5 W (or more) gives us a safety margin. (A bleeder that fails open without your knowing it is almost worst than no bleeder at all.)

A 50,000-ohm resistance with 180 V across it draws 0.0036 A (3.6 mA; voltage divided by resistance).

A high-resistance bleeder doesn't pull down the supply voltage immediately on power down, by the way; you have to wait multiple tens of seconds before the voltage comes down to a safe value. Do a run with a voltmeter connected across the supply terminals to get an idea of how far the supply voltage drops how fast. Then you can make a mental note to always wait at least that long for the bleeder to operate before working on the supply (or connected equipment) after power down. (And then use a screwdriver to short the supply terminals briefly anyway, just in case the bleeder failed open for some reason.)

Best regards,

Dave

Rob wrote:

> I was contemplating the door bell transformer idea just to show newbies it could be done.

It's a time-honored practice. Giving it a try (a) works and (b) will remind everyone that it's an available approach. And of course "doorbell transformers" aren't the only candidates. Heating-system transformers--24 V, I think, like so-called doorbell transformers--are also fine. (Home Depot, Lowe's, your local hardware store--there you go.) So are the 6.3, 12.6, and 25.2-V "filament" transformers you can get via various suppliers (Digi-Key, Mouser) and Radio Shack stores (such as you may be able to visit).

Two transformers connected "back to back" makes an isolation transformer. The practice works just fine.

Don't be tempted to use half-wave rectification (one diode) just because it's simple or because you see a published circuit doing it. Half-wave rectification is dumb because it wastes transformer power by using only a half cycle of each ac cycle. This causes a net dc flow in the transformer secondary, which unnecessarily heats the transformer.

And BTW any computer power supply will have a high-voltage bridge rectifier that you can use, as well as two identical high-value electrolytics that will work fine for a back-to-back-120-V-transformers supply. Those caps are almost always rated at at least 200 V working; that's comfortably above the peak voltage you'll get out of rectifying 120 V (peak voltage, 1.414 times 120, or 169.7 V). Your line voltage may be higher or lower than 120, but assuming it's not higher than 125, 200-V filter Cs should be fine. Just make sure those big-value caps are discharged every time you work on the supply.

Best regards,

Dave

On the subject of finding old tube type radios fo be scrapped for parts.
I have made arrangements with several Junque shops to buy all the old
radios they have. Don't find many but do find 2 or 3 a year enough to keep
me and the local in parts. I even find one every now and then that is worth
repairing and selling. not that I have made enough money to make it worth
while ... but enough to keep my interest up.
Dan.

The circuit that fueled this discussion is between "++++++++"
the power supply circuit shows just one 1N4001 diode... "half wave
rectification:"
http://www.bristolwatch.com/radio/tube_ps.gif

As per the advice......:
So for that circuit I am thinking I should replace that one diode with 4
diodes... or a bridge rectifier in this configuration
shown in this picture:
http://www.electronics-tutorials.ws/diode/diode23.gif
on this web page:
http://www.electronics-tutorials.ws/diode/diode_6.html

and also ADD the three 1/2 watt 150K ohm bleeder resistors
or two 220k, 1/2w resistors
in parallel with the smoothing capacitor
shown as C in this diode23.gif

And then finally.... add one 10 ohm fuse resistor per this advice:
==========
You could also put a 1/4w 10 ohm resistor in series with the output.
Under normal current (20 to 50 mA), the voltage and power lost in this
resistor is minimal. If a fault occurs in your radio, the resistor will
see a much higher current and burn out. That will save your rectifier
and transformer from excessive current. Consider it a cheap, low current
fuse
==========

I do have 450 volt 100uF capacitors so I don't have to scavenge power
supply parts.
Not trying to be hoity toity here.....
I would definitely scavenge hard to get expensive variable air caps from
junked radios
but I'm not real fond of scraping parts off computer power supplies.

Am am very familiar with LM7805 LM7809 LM7812 voltage regulators.
http://www.circuitdiagram.org/images/9v-power-supply-using-lm7809.GIF
I've used them a lot for transistor circuits. I have a pile of them.
I didn't think much about using sandstate regulators until I saw Leonard
Meeks circuit:
http://www.learnmorsecode.com/regenx/LM/mk21mod3c.jpg

But what solid sate voltage regulator is used for real clean B+ 90 volts?

++
12AV6 Vacuum Tube Radio shown here
http://www.bristolwatch.com/radio/index.htm

that uses a power supply built with TWO 12 volt transformers
that normally get used to step down 110 mains socket voltage to 12 volts.
++
http://www.bristolwatch.com/radio/tube_ps.gif
Pins 3 and 4 on the tube are the filament and require 12.6 volts AC or
DC. The power supply for the plate can be 150 to 170 volts. (This is a
seven pin vacuum tube.) The circuit above uses two 120 to 12.6 volt step
down transformers. By connecting the two transformers "back to back"
this serves to isolate the project from the power line to prevent
electric shock or having a "HOT" ground.
++

Yes, that full-wave-bridge coverage you've linked is exactly what you need. The 10-ohm fuse resistor is also a good idea--not only because it may save some components in the event of a long, hard short-circuit across the supply terminals, but also because if you connect a voltmeter across it you'll be able to easily calculate the current being drawn from the supply, where every 0.01 V across 10 ohms equals 1 mA of current. Don't put the fuse between the bleeder and supply, though; you don't want the bleeder to ever become disconnected, as would happen if the fuse resistor does its fuse thing.

And I forgot to mention a key operational aspect of using full-wave rectification rather than half-wave: Full-wave rectification results in ripple that's easier to filter. With full-wave rectification, the ripple occurs at 120 Hz (two pulses per cycle of the line waveform), whereas with half-wave rectification the ripple occurs at 60 Hz (one pulse per cycle). Whatever filtering you do will therefore get rid of more 120-Hz ripple than 60-Hz ripple with the same filtering parts in place.

BTW, when you rescue the bridge rectifier from a computer power supply, you can probably find out its ratings (current and voltage) by Googling its cryptic part number in conjunction with the word _rectifier_. Likewise for the non-1N-series markings on rescue rectifier diodes.

Best regards,

Dave

26452. is it OK to use NIXIE tube power supplies for B+

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-21 18:22:43 UTC
From: Rob
Topic: 26452 Message: 26452

On the web I came across a lot of NIXIE tube power supplies that are DC
to DC converters that will
take 12 volts and make up to 200 volts DC.

These circuits are based on 555 timers chips and MC34063 and MAX1771.

The attraction to these curiosities is merely the cost.....

Nixie High Voltage Power Supply Kit 40V - 200V
http://www.ebay.com/itm/131741604802 $12

and

Nixie Power supply, High Voltage Switch Mode DC-DC Converter Kit,
95-190VDC, 25ma @ 180VDC
Model # HV-SMPS $19.99

which looks too good to be true......
so I ask
is it OK to use these NIXIE tube power supplies for B+
in a 6AK5
circuit like this:
http://www.learnmorsecode.com/regenx/LM/Mk21Mod3d.jpg

I'm a bit of a purist.... rolling my own capacitors and winding
KANTHAL wire for filament rheostats.....
http://www.learnmorsecode.com/regen/rheostat24AWGKANTHAL.jpg
http://www.learnmorsecode.com/regen/resistance.jpg
http://www.learnmorsecode.com/help/type30/index.html

but I always look for how the modern world components can be used in
case it MUST be done cheaper
for fellow radio experimenters.

I always thought that power supply circuits introduce unnecessary ...
unwanted .....screaming RF.
I could walk through a computer room...yea I said room.... and could
wave my SONY WALKMAN headphone wire
close to mainframe computers and pick out where the power supply was
inside the BIG BLUE cabinets.

So what happens with these NIXIE power supplies?
Are they any use to us to experiment with tube regenerative receivers
that will hear radio transmission from anywhere on the planet?

So if you are using a single 100uF capacitor, the ripple voltage will be something like 4.2v peak to peak. It will be less at lower currents.

I'd recommend using a filter to get the ripple to less than 0.1vpp. The absolute value isn't always critical but it needs to be much smaller than the strength of the input signal. A radio receiver is going to need a very clean DC supply and that can be done easily.

On the power supply, I recommend a 100uF capacitor, a 150 ohm resistor, and another 100uF capacitor. The resistor only burns about 6v and you get a ripple less than 0.5vpp. In your receiver, on a separate chassis, you can place another filter for more reduction. The regenerative detector should draw no more than 5 mA or so.

The power amplifier plate will see, at full power, something like 200vpp, meaning that a volt or two of ripple is not going to be noticeable. Just keep that ripple put of the earlier stages.

Also, some people make a choke out of the 120v primary of a spare transformer. It sort of works. Using a choke instead of a resistor greatly reduces ripple and therefore hum.

It's a time-honored practice. Giving it a try (a) works and (b) will remind everyone that it's an available approach. And of course "doorbell transformers" aren't the only candidates. Heating-system transformers--24 V, I think, like so-called doorbell transformers--are also fine. (Home Depot, Lowe's, your local hardware store--there you go.) So are the 6.3, 12.6, and 25.2-V "filament" transformers you can get via various suppliers (Digi-Key, Mouser) and Radio Shack stores (such as you may be able to visit).

Two transformers connected "back to back" makes an isolation transformer. The practice works just fine.

Don't be tempted to use half-wave rectification (one diode) just because it's simple or because you see a published circuit doing it. Half-wave rectification is dumb because it

wastes transformer power by using only a half cycle of each ac cycle. This causes a net dc flow in the transformer secondary, which unnecessarily heats the transformer.

And BTW any computer power supply will have a high-voltage bridge rectifier that you can use, as well as two identical high-value electrolytics that will work fine for a back-to-back-120-V-transformers supply. Those caps are almost always rated at at least 200 V working; that's comfortably above the peak voltage you'll get out of rectifying 120 V (peak voltage, 1.414 times 120, or 169.7 V). Your line voltage may be higher or lower than 120, but assuming it's not higher than 125, 200-V filter Cs should be fine. Just make sure those big-value caps are discharged every time you work on the supply.

RF chokes are useless for reducing ripple in a power supply. You need an inductance on the order of henries, commonly a value between 5 and 30 H (with higher values needed for lower current). RF chokes are millionths or thousandths of henries. The resistor method is fine. 470-ohm, 10-W wirewound power resistors are fine.

Yes, your ASCII-art drawing is correct.

Power transformers don't want to see dc in their windings (it causes their cores to _saturate_), so don't use one to approximate a power-supply choke. Use the secondary (higher-impedance winding) of an audio output transformer instead if you must substitute.

But resistors and high-value capacitors can do a good enough job of filtering without your having to resort to chokes, and nowadays we can pour on hundreds of microfarads of electrolytic filter capacitance at relatively low cost, saving on the cost of chokes (a lot of iron wrapped up in some copper). If you're going to use anything other than an audio-output-transformer winding (as an experiment; at least _they_ expect to see dc in their primarie windings), get an actual filter choke. The exact value needed (to make a difference in ripple reduction) "depends"; go read one of the ham handbooks about power supplies. (PDFs available from tubebooks.org; use a handbook from the 1950s or later.

As far as audio output stages go, assuming that you use a beam power tube (6V6/12V6, 12A6) or power pentode (6K6, 6AK6), a cool fact about such tubes lets you ease up on filtering requirements somewhat. The plate current of a pentode or beam tube depends more on its _screen_ voltage that its plate voltage. This means that you can tolerate more ripple on the _plate_ supply to an AF power tube than on its _screen_ supply. Screens take relatively little current compared to the plate, so you can extend your filter one section more just for the power-amp screen (and maybe another highly-hum-sensitive stage) and power the power-amp screen from the extra-filtered supply.

Your Walkman like heard power supplies inside computer cabinets by means of induction. (You may alos have heard noise near the supplies merely because that's where the noisy ac line came in.) That mechanism won't operate much with a dc-to-dc-converter supply. What will matter more is how clean the output line is in terms of noise and RF junk. (Dc-to-dc converters include an oscillator that can generate harmonics.)

The best way to find out if one of these supplies will work is to get one and try it. So many factors are in play as to whether or not such a supply compromises radio reception that generic/general statements are unlikely to be useful.

He's proposing a 150k resistor as the series element. Use a 150 ohm resistor (470 ohms is fine if you can tolerate the extra voltage loss) for the series element between the two capacitors. The 150 will burn 7.5v and 0.375w. A 1/2w resistor will get hot here and a 1w resistor will get less hot.

A 470 ohm resistor will burn around 24v at 50 mA, which is a little over a watt. Use a 3w resistor. The ripple output using a 150r is around 350 mvpp and it's around 115 mvpp with the 470r. You can do either one and you'll see low ripple either way.

If you used a 1.5H choke, the output ripple would be lower than 50 mvpp. The advantage is that you don't lose as much DC voltage as when you use a resistor. Either one will work well for you and you'll remember that the same filter will show lower ripple voltage when you are using less current from the supply.

As a rule of thumb, use a resistor that is more than twice the power of what you calculate. Remember that it will still put off heat but will get less hot itself.

One more thing. If you use a regulator tube, you can get a steady 105ish volts for your receiver and use the 170v output for the audio amplifier. I'll draw you a diagram.

Yes, chokes are better. I think he'd need more than 1.5 H, though, as what's missing from this discussion is the concept of _critical inductance_, input-choke values lower than which will, at low current demand, allow the supply output to soar as if it's a capacitor-input filter. (That's why a constant minimum load like a VR tube is a good thing in addition to the VR tube provided a constant-V output. Whatever constant draw the VR tube contributes helps bring the min input-choke inductance value down.)

The formula for critical inductance is Lcrit = Output V divided by min current drain in mA. If this were a 150-V supply, for instance, a choke as low as 1.5 H would need a min current drain of 100 mA to keep the choke in full play. Still assuming 150 V, a bleeder current of 3 mA (50 k bleeder) and a VR-tube max current of 20 mA would set a min current drain of 23 mA, making Lcrt 150 / 23, or 6.5 H.

In the days of no transistors and thermionic/gas-vapor rectifiers, heavy bleeder currents were commonly used to keep chokes choking. So were _swinging chokes_--chokes manufactured to emphasize the normal choke tendency for inductance to decrease as current through the choke increases. [The first choke in the line was the swinging choke; the next and subsequent chokes were _smoothing_ chokes.] All chokes swing somewhat, so whatever choke you buy will have its inductance specified at a given current but will exhibit some inductance increase as the current through it decreases.)

Hammand (via tubesandmore.com) has a 15 H, 75 mA job (411 ohms) and a 9 H, 40 mA job (300 ohms). Either would work in this application, I think--and BTW I recommend the 12A6, 7701 or 5686 as equivalently good AF power output tubes for this application. All of these will draw only 20 to 30 mA max at 150ish volts. My utility AF amplifier/filter box (http://dpnwritings.nfshost.com/ej/pictures/pictures0.htm http://dpnwritings.nfshost.com/ej/pictures/pictures0.htm) uses a 12A6 or 7701 day in and day out and provides excellent service at 150 V or so. An output transformer that provides a 7-kilohm load is just right for all the tubes mentioned.

Best regards,

Dave

That's assuming he wants to make a choke input filter. The capacitive input filter I outlined in my drawings uses the choke as a smoothing filter. I calculated a very low ripple with a 1.5H choke. That's also at 50 mA, which is a sizeable load current for a low power amplifier and a simple receiver. If he is just running a one-tube receiver and nothing else off of the power supply, the ripple will be ridiculously low.

> The formula for critical inductance is Lcrit = Output V divided by min current drain in mA. If this were a 150-V supply, for instance, a choke as low as 1.5 H would need a min current drain of 100 mA to keep the choke in full play. Still assuming 150 V, a bleeder current of 3 mA (50 k bleeder) and a VR-tube max current of 20 mA would set a min current drain of 23 mA, making Lcrt 150 / 23, or 6.5 H.

Yes. The objective is to make the choke equal to or higher than the effective load resistance. That's all well and good, and makes the current waveform from the transformer closer to a sine wave. That means you can reap more current from the transformer. Still, using the 1.5H inductor as a pi filter instead of an input choke is still effective at reducing ripple.

> In the days of no transistors and thermionic/gas-vapor rectifiers, heavy bleeder currents were commonly used to keep chokes choking. So were _swinging chokes_--chokes manufactured to emphasize the normal choke tendency for inductance to decrease as current through the choke increases. [The first choke in the line was the swinging choke; the next and subsequent chokes were _smoothing_ chokes.] All chokes swing somewhat, so whatever choke you buy will have its inductance specified at a given current but will exhibit some inductance increase as the current through it decreases.)

Indeed. I'm not going to suggest that we use a lot of bleeder current because that's effectively wasted until the power switch is opened. If he built a supply that were capacitor input, followed up by two LC smoothing filter stages, there would be so much ripple reduction that it might take a sensitive direct conversion receiver to detect it.

> Hammand (via tubesandmore.com) has a 15 H, 75 mA job (411 ohms) and a 9 H, 40 mA job (300 ohms). Either would work in this application, I think--and BTW I recommend the 12A6, 7701 or 5686 as equivalently good AF power output tubes for this application. All of these will

draw only 20 to 30 mA max at 150ish volts. My utility AF amplifier/filter box (http://dpnwritings.nfshost.com/ej/pictures/pictures0.htm) uses a 12A6 or 7701 day in and day out and provides excellent service at 150 V or so. An output transformer that provides a 7-kilohm load is just right for all the tubes mentioned.

Yes. Before the advent of 12v-plate tubes, there were many tubes made with 12v heaters designed to be run by 200-ish volts from a vibrator supply. There are very many power pentodes or beam power tubes capable of a watt or two. I'd suggest that as the starting point for the amplifier.

I'm going through a similar issue right now. I have a 220-110v power transformer I got in Bahrain that is 300w of iron and copper. I calculated a maximum DC current of 500mA which is more than almost any amplifier would need (unless I had an output stage of eight 6L6s in push-pull). Finding a hefty choke capable of that kind of current is tough. One of my mentors has sent me a 10H, 375 mA choke which I'm going to use. I intend to make a CLC filter for the power supply, using a 470 uF cap as the input capacitor. It's possible I'll get another cap that large for the other spot in the filter.The whole thing will power a transmitter and receiver. For a starter transmitter, I'm thinking 6C4s in parallel or push pull or something.

Dang.... I just purchased two of the 2H chokes per the drawing
instruction of of "2H or more".

The prices on the 15H chokes are back out there in the $30 range.....
while TWO of the 2H chokes can be purchased for $30.

I always try to buy at least two components.... one for home and one
for radio club show and tell
and ELMER experimentation.

I must thank both of you guys for all these details and food for thought.
The idea of doing the audio amp plus power supply AND also the OC3 tube
to power the regen experiments
is just brilliant. I really like this idea.
I can see how investing the money into the right transformer and the
right choke once will pay off
in the long run of future experimentation.

Its not that I MUST rebuild something antique per original
specifications......
I just wanted to get off the 9 volt battery pile.
So I'm game for anything here... maybe even the $12 NIXIE tube power
supply if it isn't noisy.

You're on the right track. If you have an extra capacitor, make a CLCLC filter with the two chokes, that will reduce hum so much it will be hard to measure.

The regen will benefit from a stabilized supply voltage in that its frequency stability will improve as a result of regulation. Most VFOs I have seen use a zener diode for the same reason.

That's true. There's smoothing/filtering and then there's supply voltage regulation. Especially if the receiver isn't a many-tube superhet with AGC, the power supply load won't vary much at all during operation. Even just a few henries, especially in conjunction with the multi-hundred-uF caps available cheaply today, will still provide very useful ripple reduction.

To keep us all on these same page: All an inter-filter-C resistor does to help filtering is slow discharge of the capacitor[s] ahead of it. But using a choke--an inductor--instead does that and more. The "more" is that the choke stores energy in its magnetic field. Every time current through the choke starts to decrease, its magnetic field collapses a little, "trying" to maintain the current flow through the choke; likewise, every time current through the choke starts to increase, some of that increase goes into strengthening the magnetic field around the choke and slowing the buildup of current through the choke. In effect, the choke smooths ripple _by resisting changes in the current flow through it_.

A filter capacitor reduces ripple by storing energy in an _electric_ field, and sourcing energy from that field when the voltage across its terminals starts to drop (such as between charging pulses from the rectifiers that charge it). So building a power-supply filter with parallel capacitors (supply line to ground) and series inductors (in series with the supply line) irons out ripple "coming and going." The capacitors prop up the supply voltage when voltage starts to sag; the inductors prop up supply _current_ when _current_ starts to sag. Ripple (ac superimposed on the supply's dc output) is just a small cyclical sag that we want to iron out.

And BTW if we want to think of a power-supply filter as a big low-pass filter, that works, too! Ripple is just a frequency compoment we want not to show up superimposed on the supply's big dc output signal.

> Yes. Before the advent of 12v-plate tubes, there were many tubes made

We see a slew of these coming out in the 1950s, when cars were switching from 6.3 to 12.6 V electrical systems. The 12BK5 comes to mind; but note that for cars, low heater drain was not as important, so some of the automotive power tubes take a _lot_ of heater current at 12.6 V (0.6 A for the 12BK5). Another candidate that's cheap on Ebay is the 8106; it was an RF driver for the GE Progress Line transceivers, but will work well as an AF power tube.

(Use a 100- or 1000-ohm stopper resistor between its screen and the outside world, though; the thing has transconductance of 9 mS!) The reason I like the 12A6, 7701, and 5686 is that they were intended for _aircraft_ use and so embody heater-power economy as well as lower-power plates. Every "ARC-5"/"Command" receiver had a 12A6 AF power stage.

And BTW although they're fun to play with, those "12 V plate" tubes were pretty crummy performers compared to their higher-voltage counterparts. I just added this passage to a "Ministry of Silly Tubes" page I'm working on for my site:

Wrote Vern Chambers, W1JEQ, in his "Something New in High-Frequency Mobile Converters," QST, 1956, pages 16–21:
As might so very well be expected, there is one small fly in the ointment as far as the new tubes are concerned. They do overload at signal levels considerably below that handled with ease by conventional high-voltage tubes. However, in actual practice, we have run across only one or two ham-band signals that caused the converter to "fold up." All other cases of overload have been effectively treated merely by detuning the input circuit.
And BTW, the usage "silly tubes" is just for the fun of invoking Monty Python. What the page is about (draft in beginning stages at http://dpnwritings.nfshost.com/ej/silly_tubes/ http://dpnwritings.nfshost.com/ej/silly_tubes/) is that if we're willing to get off the beaten path and not just try to build yesterday's circuits again and again with exactly the same tubes and practices as "yesterday" involved, a large array of very fun tube candidates await. Of _course_ I've got meself a clutch of those 12-V-plate/screen tubes to play with, for instance; but I also have a series of experiments planned to build a Regenerodyne that tries 3DT6 v 3BY6 v 3BE6 converter ahead of a 9GV8 detector/AF-amplifier combo (with the _power pentode_ as detector). Two sleeves of Amperex 4ES8 dual triodes for ten bucks--remote-cutoff cascodes, here I come!--were hard to pass up. There's a wide world beyond 6AG7s, 6L6s and 807/1625s, and especially if we're willing to use tubes with odd heater voltages, we pretty much have a lifetime supply waiting for us at hamfests and Ebay.

> For a starter transmitter, I'm thinking 6C4s in parallel or push pull or something.

A triode the audio, er, enthusiasts so far haven't price-bombed is the 6S4, A pair of those in push-pull should make a peachy low-power final much herkier than one based on 6C4s. They're low-mu like the old days, but high-transconductance like the new days.

Best regards,

Dave

No problem! As Ed wrote, 2 H can still contribute very useful ripple reduction in your power supply. The "critical inductance" aspect I discussed is more about supply output-voltage regulation--an issue that doesn't matter much for receivers, especially simple receivers. Getting an 0C3 or 0B2 (equivalent VR tubes, the first octal and the second, 7-pin mini) to peg the voltage feed to your detector will make your detector noticeably less botherable by line-voltage shifts, such as when big electric appliances in the house cycle and switch. Even just one of your 2-H chokes will, in place of an inter-C resistor (a) give less voltage drop and (b) give better ripple reduction.

And BTW, "for a good time," try this: If you have a receiver with a triode AF voltage amplifier or (even better) a pentode AF voltage amplifier, temporarily remove its plate resistor (usually something between 47 k and 150 k) and connect one of your 2-H chokes in in its place. Then solder two 0.01-uF capacitors in parallel across the choke. This makes an audio tuned circuit (0.02 uF across 2 H) that will resonate in the vicinity of 800 Hz. See what tuning around for ham Morse-code transmissions sounds like with a distinct 800-Hz peak in your audio. The choke will pick up some hum, and the overall gain will probably be less than with the resistor you removed, but this gives you a glimpse of the possibilities of "tuned audio" with a regen.

Best regards,

Dave

I don't know about the module under discussion, but one I bought had wrong type filter capacitors in it. Plain old lyrics , rather than a low ESR parts. It got quite hot in operation. Replacing it with a film capacitor helped a lot. So, you might look out for that. Regards, Mark KB9VKE -----Original Message----- From: J Ed jedwardsat1@... I've got four 0C3 tubes coming from different sources around the planet.
Don't know when they will arrive.

re...good time:

Is there any particular radio schematic that documents that CW enhancement
and
or
how to design to eliminate the hum?

What is the frequency of that hum? Line voltage 60Hz ?

Would it be advantageous to design an audio stage highpass output filter
that simply passes no low frequency below 200Hz
which would eliminate hum and provide crisp CW ?

Depends on line frequency and type of rectifier circuit. With 60 cycle line a half-wave rectifier gives 60 cycle ripple/hum. A full wave rectifier gives 120 cycle hum. Note that audio transformers, inductors, and even audio output transformers are efficient hum pickup coils, which is why it is wise to put the power supply on a separate chassis far from the receiver. Once-upon-a-time I had a Collins 75A-2 with the output transformer mounted next to the power transformer, and it had noticeable hum. I removed the output transformer, put it on long leads and moved it around the chassis trying to find a hum-free place, and there was NO place that was hum-free. I finally mounted it behind the PTO at an odd angle for minimum pickup.

The stray magnetic field from transformers increases exponentially with applied voltage, so you can dramatically reduce hum pickup by reducing input voltage, say to 110 volts or less, with no degradation in receiver performance.

Rob wrote:

> Is there any particular radio schematic that documents
> that CW enhancement and or
> how to design to eliminate the hum?

No. I mentioned it as a fun experiment based on my knowledge of _general_ practices in the late 1920s and early 1930s. Typically the tuned circuit used was a tuned Ford spark coil in the plate circuit of a tetrode or pentode AF voltage amplifier. (Tetrode or pentode was better than triode because the high plate resistance of such tubes loaded the AF tuned circuit less, increasingly selectivity.)

> What is the frequency of that hum? Line voltage 60Hz?

60 Hz and harmonics of same. Depending on the source and the transducer (choke), it may sound somewhat musical. It'll also change in timbre as the choke is rotated/moved as a result of variable coupling to various sources. As Richard has mentioned, of course, one's power supply is a major source of possible such hum. Keeping it inches to feet away "outboard" is a good idea. (Keeping power-supply heat away from receiver tuning circuits also minimizes warm-up drift.)

> Would it be advantageous to design an audio stage highpass output filter that
> simply passes no low frequency below 200Hz which would eliminate hum and provide crisp CW
?

For hum and 120 Hz and lower, maybe; but much of the hum you hear will be harmonics of 60 Hz and of 120 Hz, and right in your audio passband.

Again, I mentioned the choke-as-tuned-AF-filter idea as something fun to try, and from which you can learn and experience. An open-frame filter choke will pick up a lot of stuff because physics allows it to and isn't a good choice for passive filtering because (a) it picks up lots of stuff and (b) it's relatively low-Q. (Low Q equiates to broader peaking.)

What I do at W9BRD is use selectable passive _low pass_ filtering selectivity. The LMI-series filters by UTC (go to Ebay and search on UTC filter, and look for hits that aren't filter chokes; and also you can surely buy LMI-1000s from Surplus Sales of Nebraska (display the page at http://surplussales.com/Filters/Filters-1.html http://surplussales.com/Filters/Filters-1.html and search for "LMI-1000" in it). Anything more than $20 for one of these filters is overcharging.

I have switchable 400, 500, 800, 1000 and 3000-Hz filters in my utility filter/amplifier box (http://dpnwritings.nfshost.com/ej/pictures/pictures0.htm http://dpnwritings.nfshost.com/ej/pictures/pictures0.htm ; those pix were taken two filters ago) and they give me everything I need for two-way CW work. (Also have a "through" position to entiresly bypass the filters.) No, I don't have a schematic of the thing available at the moment.

By the way, the idea of building one's power supply in an outboard box, or building an AF filter/amplifier box, serves another important goal: These parts are relatively hard to find and cost more and more over time. If you'll use just one receiver at a time, why duplicate functionality in it that just sits there while another radio is in use? So I have stand-alone ("outboard") power supplies, and my AF/filtering circuit is stand-alone/outboard, and Molex connectors and RCA jacks and patch cords let me mix and match the receiving heads that drive them. One of my power supplies is based on the power transformer from an A-2516 receiver; its AF output transformer is inside the AF amplifier/filter box. Why have unused power and AF transformers (and handfuls of nice passive UTC filters) sitting in unused radios? I pretty much build just _tuners_ -- remember that concept from the 1950s/60s/70s audiophile days? -- and swap them in and out while the power supplies and AF/filter box stay the same.

Best regards,

Dave

More on hum:
Another thing to try is a shorting copper band around the entire power transformer. "In theory" no flux can exist outside the band. It isn't that great, but I saw a reduction in hum.

The worst case I've seen is the Conar receiver. The power transformer is grossly overdriven and spews magnetic flux all over the receiver, even inducing ac into the IF transformer windings. I changed to a full-wave bridge rectifier, oriented the output transformer for minimum pickup, added the copper band, operated it at 100-110 volts, and it turned into a decent receiver.

All interesting, with a of of good points presented.

When I designed my 1V3 LF Regen receiver (5 tubes in a 7 tube + Rect circuit counting the two double triodes, I started out with a basic premise. I then went on a parts scavenger hunt that turned up a number of items that caused me to revise (and improve) on what I'd originally come up with.

I needed all the 'iron' (power Xformer, filter choke, output Xformer etc, so I redesigned around what the parts search turned up. Over the past 60+ years I've done a LOT of work on tube type circuits, receivers, Xmitters & HiFi/Stereo stuff. So I have a good background to work with.

While I don't recall the exact specifics of the scrounged parts, the power transformer didn't have a center tap HV secondary, so instead of the usual half wave rectifier (for esthetic reasons I wanted to use a 6X4 rectifier), I ended up using 4 1N4007 diodes in a bridge circuit. I WANTED full wave as it's easier to filter 120CPS. When I built the receiver I hadn't yet bought my LCR meter, so I was unable to determine the exact value of the recycled DC Filter choke. I chose to use a Capacitor input filter, input capacitor is 47uF, the output capacitor from the choke is 47uF, then a 1.8K resistor followed by a 22uF filter capacitor. Following this is another 1.8K resistor that feeds the 0B2 regulator tube. The filtered B+ is for all practical purposes "battery pure", measuring under 50mV at the output of the filter choke, under 4mV across the 22uF capacitor (after the first 1.8K resistor) and 'zero' across the 0B2 regulator tube.

1. The audio output stage gets it's B+ from the output of the filter choke.

2. All other audio stages get their B+ from the output of the first 1.8K resistor (across the 22uF capacitor).

3. The entire RF section, 6AK5 RF amp, 1/2 12AU7 Armstrong Detector & the 1/2 12AU7 cathode follower (to feed external counter) receive their power from the 0B2 regulator.

3. To prevent "hum coupling" from the 6.3 VAC filament wiring, both sides of the filament string are floated above chassis, there is a 100 Ohm "Hum Balance" pot across the filament string whose center tap grounds to the chassis. In addition, there are .01uF capacitors from each pin of the 12AU7 to ground. This to keep both sides of the filament at RF ground potential (not sure that was needed).

THERE IS NO 60/120 CPS HUM IN THE BASIC DESIGN OF THE RECEIVER. Just a very little bit is coupled from the power Xformer coupling into the three audio chokes (adjustable 4-12H) used in the audio filtering. At first I found it distracting, but redesigning/rewiring the AF gain distribution, filter location in the chain of the AF sections basically eliminated it. . .

****

The audio filtering section.

When I went on the parts scavenger hunt I was offered three adjustable 4-12H AF chokes that had been removed from an AF filter by their 'donor'. They have three connections, one being a center tap. I used appropriate parallel capacitors to 'tune' them to 400, 600 & 1020 Hz (400 & 1020 being the modulation frequencies of most of the NDB's in the world). The filters are installed in a steel box to reduce any magnetic coupling from the power xformer. There are 6 audio bandwidths selectable via a front panel switch. They are

1. Wide (no AF filtering).

2. 400CPs.

3. 600CPs.

4. 1020CPs.

5. Low-Pass 1 (resistor/capacitor LPF, treble cut).

6. Low-Pass 2 (resistor capacitor LPF, steeper treble cut).

Overall I'm extremely pleased with this receiver, it has provided a LOT of NDB DX in the longwave range (tunes 150-530KCs in two ranges).

See pictures here. . .

Sorry no pictures, the Nixie power supply module I bought used MC34063 but that doesn't matter. The switching frequency is what matters with regard to the rectifier and output filter capacitor immediately following. Both have to be high-speed capable parts. Don't worry too much about this; this is just my experience with only one module. Yours may be different. when you get your module, fire it up and see how hot the capacitors get. They should not feel warm at all. If they do, that's a sign of a high-ESR part. OTOH for a 60/120 Hz based power supply, the rectifier speed and capacitor ESR is not important at all. Any parts you have will work fine. Regards Mark KB9VKE -----Original Message----- From: Rob roomberg@... Richard wrote:

> The worst case I've seen is the Conar receiver....

There's always more to learn, and it's fun even when annoyance is the driver. I learned in a page on the JR-500S receiver (the Trio-branded version of the Allied A-2516 receiver) that one of the weaknesses in that design is that the B+ rectifier is at one side of the receiver and the multi-section filter cap is at the other side, with a run of something like 9 to 11 inches of wire connecting the rectifier (half wave!) to the first filter cap. The relatively high-current charging pulses to the first cap zip through that long wire run, inducing hum into adjacent circuitry along the way. Cure: Move at least the first filter cap (using a separate capacitor) to a spot right next to the rectifier. (And of course change the rectifier to full-wave. The A-2516 power transformer runs very noticeably cooler to the touch with full-wave rectification.)

Another hummerific experience awaits owners of the Heathkit HR-10 receiver. Some years back, as I awaited the arrival of one from an Ebay purchase, I read the following in George Grammer's review of the receiver in July 1963 _QST_:

"Aside from this, the only thing that can be criticized is the hum in headphone reception. This is not simply a matter of plate-supply filtering--more filter was tried with little improvement--but appears to be tied up with a.c. currents arising from the heater wiring. It goes through a minimum at a rather high setting of the audio gain control, at which point it can be fairly well masked by noise and signals at high settings of the r.f. gain control, if your eardrums can sand that much volume. An external attenuator for the headphones would probably help in this respect."

When my HR-10 arrived and I got it going after some preventive re-capping, there was that exact hum, complete with the partial null occurring at a point short of the high end of the AF GAIN range. (That a null occurs means that the hum we hear comes from at least two different paths, one from before the AF GAIN control and another after. The two (or the two main) sources are out of phase, so setting one path to the right amplitude cancels the composite hum, at least pretty much.) Oh, ho, I'll fool you: I'll rewire the output tube as a power cathode follower (with no output transformer to pick up hum). Same hum! Okay, no chassis return for the heater wiring; I'll lift the ground returns for each stage, run _two_ wires, and balance it out. Nope; no change. All right, then, external dc supply for the heaters. Same hum! Scrap time!

Every millisecond spent abating or avoiding hum I consider to be time wasted (time that could have been spent on radio). I especially have no sense of humor about self-inflicted problems that arise from using a big audio signal to heat tubes that...duhh...amplify or generate audio. I love me my 13-V, 4- and 30- amp dc supplies! (And psst: One reason hum with Yesteryear's receivers was more tolerable was that communicators didn't listen with hi-fi headphones. In particular the magnetic headphones popular in the heyday of the regen had almost no low-end response, and popular receiving pitches were more likely to be nearer

to 1000 Hz than below 500.)

If you're using ac-heated tubes without hum problems, good for you! I am and will remian unmoved. :-)

Best regards,

Dave

I'll go quiet now until the tubes and transformers and chokes arrive
from China, Russia and Italy.
Thanks for all the input from everybody.

Yes, and it can be subtle. the RAL receiver, a very good regen, has a wee bit of hum which the instruction book says can be used as an indication that it's working properly. It's due to pickup in the audio filter inductors from the heater wiring. Switch out the low-pass filter - no hum. DC on the heaters - no hum. I'm a hum-bug.

26478. Re: [regenrx] NIXIE tube power supplies for B+ ESR not plain electrolytics

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-22 22:30:34 UTC
From: msalbert@...
Topic: 26452 Message: 26478

One more post about the nixie power supply ;-) The particular module I bought is still on ebay
http://www.ebay.com/itm/High-Voltage-Power-Supply-Kit-45V-to-190V-Out-for-Nixie-Old-Radio-Kit-/252389307492?hash=item3ac3933464:g:u-oAAOxyq5NRDbye#ht_962wt_1246

you can download the instructions and schematic from the listing. The capacitor I changed from lytic to film was C4, a 2.2uF/250V. I noticed they now mention changing this cap as an improvement but don't say what type capacitor the new part is. Also, I found the solenoid inductor was a source of RFI to nearby radios. Changing that to a toroid or putting the whole rig inside a metal box may help but I haven't tried any of that.

Hope this helps!
Regards
Mark KB9VKE

Hello Mark,

I ordered two power supplys referred to in the link above, from the person at the same link.

When the card arrived it didn't work, and after a few minutes I saw the switching FET was reversed.
I described the problem to Tortugascuba (who sold it) and he claimed the card was supplied as a kit, not assembled. Well - he was wrong. I'm clever enough to recognize the difference between a kit and and an assembled card.

My point in complaining was this - if I touched the board - the problem was mine.
It was his problem, and he should have fixed it.

I fitted a replacement FET (an easy task) and the card worked.
In the end I got two boards that worked, and the cost of the FET I supplied was close to "zip".

I haven't used the board "on air" so I can't make a comment on whether it generates noise (or not).
I imagine you won't hear it when it's inside a diecast box, with a choke on the supply lines.

Les

26480. OC3 base

That's a standard octal tube base with two pins omitted that aren't used. Any old octal socket will work fine.

I bought an LED street light with no documentation.
Does anyone have one of these and can anyone tell me how to wire it to household mains?
It has a tag that says AC220V so I am assuming that means it gets connected to two opposing
rails of the 110V circuit breakers just like a stove or oven or hot water heater....

but which wires?

Robert,

That looks like a standard Octal Tube base, very common in the 40's-50's
(and maybe earlier).

I have some 'recycled' ones, and if you need it can mail one in a padded
envelope, though it'll probably be at least a couple days before I can.
Wifey is being released from Anberry (Physical rehab) in about an hour
and I expect the next couple days will be pretty hectic.

I figured it out.
I opened it up and saw the blue and brown wires connected to the power supply marked
line and neutral.
http://www.learnmorsecode.com/regenx/choke/streetcontrol.jpg

The yellow ground wire is not connected.

It definitely is a pure white light street lamp..... and at 36 watts is just another space age win for technology saving the planet.

Blue is neutral, Brown is hot. Per the European wiring color standards. Green/yellow is ground. Looks interesting, let us know how it works out. Shouldn't require much power; rather than running 220v to it a small step up transformer might be more convenient. Regards, Mark KB9VKE -----Original Message----- From: Rob roomberg@... [regenrx] To: regenrx Sent: Wed, May 25, 2016 03:26 PM Subject: [regenrx] how to wire an LED street light I bought an LED street light with no documentation. Does anyone have one of these and can anyone tell me how to wire it to household mains? It has a tag that says AC220V so I am assuming that means it gets connected to two opposing rails of the 110V circuit breakers just like a stove or oven or hot water heater.... but which wires? http://www.learnmorsecode.com/regen4/streetlight2.jpg ---------- Posted by: Rob <roomberg@...> ---------- "In the interest of Regenerating radio's lost art of Regeneration" ---------- Yahoo Groups Links

26491. How to test a power supply choke

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-25 23:54:09 UTC
From: Rob
Topic: 26436 Message: 26491

New 1.5H choke costs $15.
22 gauge wire costs $5 at WALMART.

Not sure how to test unknown chokes.
Not all the parts arrived yet to build all the power supply but I am curious
how to know if I got the desired result or if this was a really bad idea:

It cost $32. Works great on regular 110 AC.
The unit is definitely designed for USA service, not the labeled AC220V
3 wire configuration.
Image shows how it was shipped... I did not change anything. I just
removed the cover and took the picture.
http://www.learnmorsecode.com/regenx/choke/streetcontrol.jpg
The yellow wire was floating free in the case.

I will definitely install more of these.

From: Phil
Topic: 26436 Message: 26493

Thank you.

I've found the quality of the Chinese ceramic sockets varies widely.
When I built my regen last summer I ordered some ceramic 7 pin, 9 pin
and octal sockets. The 9 pin were good, (had tube shield bases and
shields), the octal were good, but the 7 pin were terrible. They
consisted of a ceramic base which the socket pins slid into, then the
pins were held in place via a thin and brittle wafer. The wafer of
every one that I tried to use broke into pieces and the pins fell out. I
junked all of the 7 pin ones and used some that came from a parted out
piece of gear.

You can get 24g wire from ethernet cable as it's made from four twisted pairs. For currents under 100 mA you should be fine. To ensure that it doesn't suffer voltage breakdown, you could get or make plastic standoff pieces to ensure the wire isn't accidentally contacting a grounded piece of metal so insulation breakdown occurs.

To test the ripple of the circuit, you need an oscilloscope and a capacitor to block the DC from the supply. Drawing current from your supply, you can measure the AC ripple from the supply. Unloaded, the power supply will show very little ripple.

Not having a scope, you can hook it up to the radio in question and turn the gain up. If you hear hum at an objectionable level, more filtering is needed. This is a reason that direct conversion receivers are recommended to be run with batteries...the normally have around 100dB of audio gain and so the ripple needs to be reduced to a ridiculously low value.

As for filter chokes, you need to measure their impedance while running a DC current through them. The inductance changes with DC in the coil and to properly test the choke you need to recreate it's operating conditions. Another thing you could do is build a power supply with it, measure the ripple in and ripple out, then use that to calculate its inductance value.

Phil wrote:
> I've found the quality of the Chinese ceramic sockets varies widely.

Three things to watch out for:

1. They usually arrive with the pins slightly bent _in_ toward the center hole. Resist the urge to bend them further back then enough to make them stick straight up. Bend them further back--as you would with any classical socket--and the pins will tend to fall out.

2. They lack solder guards. What this means is that if you apply much more solder than that necessary to bond/weld your wire(s) and fill the pin's solder hole the solder will run down into the pin and freeze the pin's ability to open and close around the tube pin.

3. Initial installation of a tube in a new Chinese socket requires _a lot_ of force -- much more than you've ever needed to apply to an, er, onshore socket. Once I figured this out I first-time-install a dispensible tube in case a pin-to-glass seal might be overstressed. (Wear a leather glove in case the tube shatters.) _Or_ I find a thin steel rod/wire the same width as a tube pin, and use it to pre-form each of each socket's pins before I install a tube for the first time.

According to the power supply module label it has a wide-range line input capability. So yep 120 or 240 should work fine, or anything in between.
The green/yellow wire should be connected to the case somehow, definitely for safety and possibly for shielding purposes. Looks like maybe somebody forgot to do that :-)
Curious, where did you find it? I might send the link to my towns' street department . . .. they're still screwing in mecury vapor lamps . . .

Yes... I have a 20mHz scope :
http://www.learnmorsecode.com/help/cwrelaygood.jpg
and
digital VOMs

and LC meter
http://www.learnmorsecode.com/help/bookcap4.jpg
http://www.learnmorsecode.com/help/rfcoilandferrite.html
http://www.learnmorsecode.com/help/7rfcoilandferrite.jpg

and since I never played with high power... tube power ... I am a wee bit spooked by the idea
of hooking up my expensive tools... scopes and digital meters... to 100 volts without some instruction.

bought at don't laugh.....
banggood.com

Seems banggood is really on the ball.
I had an item not picked out of stock and within one day got a refund
and an OUT OF STOCK email asking
me if I wanted to wait 2 weeks for re-stocked item or get a refund.

I found this same streetlight advertised by a USA company for $260.
Apparently they get those local government contracts where a hammer
costs $1,000

Rob wrote:

> I don't have anything that looks like this base with a keyed center pin.

So the pin numbering works as follows:

1 Just as in your photo, orient the tube/socket so its indexing key/ridge is straight up and down and you're looking at the bottom of the tube. (We always count tube pin numbering looking from the bottom.)

2 Pin 1 is the pin to the immediate lower left of the indexing ridge.

3 Count pins clockwise (starting low, sweeping up to the left, right across the top and back down to the lower right) from pin 1. (Yes, I explained what "clockwise" means. It's a term that's going away, just as did the referent for the in-joke in "This is Rip Read with the news.")

Counting pins in this way, we see that in your photo, pins 4 and 6 are absent. As others have mentioned, this is not a flaw, but its done for economy. For instance, power tubes with the same basing as the 6L6 almost always, if not always, have Pin 6 absent. It's about economy. ("Pinout" came in with integrated circuits, BTW. Tube people always said "basing. :-) But nowadays I may throw in "pinout" to see who flinches.)

4 And so the pin to the immediate lower _right_ of the indexing ridge is pin 8.

We count pin numbers the same way on all tube sockets. Only the indexing varies: In miniature tubes and magnoval tubes, there's a gap between pins 1 and 7 (or 1 and 9), and with the gap down, pin 1 is the first pin at the left side of the gap. Likewise for Compactrons (12 pins). For big old 4, 6, and 7 pin sockets, two larger pins (the filament/heater pins) are like the indexing gap, and with the big pins down the big pin on the left is pin 1. (5-pin sockets--as for the 56, 76 and 807--_had_ to be different; all their pins are the same size, with the two close-together pins [1 and 5] serving as the index.)

You don't have to wait until your tube sockets arrive to start using your 0C3, BTW. Octal pins are spaced far enough apart so you can clamp a small alligator or crocodile clip down on one (preferably axially) without short circuiting to adjacent pins. Lay the tube on its side, maybe on a cardboard pad, secure it to the chassis with a strip or two masking tape, and connect to it with the clips. As long as you won't be doing Immelmann turns or barrel rolls with your radio bench, this will be fine until you can socket the tube properly. (Not all tubes will tolerate lying on their sides during operation--tube manuals will tattle on which ones don't--but VR tubes will work fine in any position.)

Temporary alligator-clip connections are easy for a voltage-regulator (VR) tube like the 0C3, because you have only two connections to make to it: Assuming that the negative output terminal of your supply is the same as chassis/ground/common, Pin 2 (cathode) goes to circuit common/ground/chassis and Pin 5 (anode) connects to your power-supply positive

terminal via a dropping/current-limiting resistor of the appropriate value. And then whatever you want to power from the voltage regulated by the 0C3 also connects to the 0C3's anode/plate pin (pin 5).

Fun fact: Pins 2 and 5 on _miniature_ VR tubes correspond. So once you learn "5 to positive, 2 to ground" you know all you need to know about the basic connections for octal and 7-pin-miniature VR tubes.

Fun hint: Don't directly shunt a VR tube with more than 0.1 uF, otherwise you will likely build a very slow relaxation oscillator. VR datasheets usually mention this.

Best regards,

Dave

26503. Why are there internal connections between unused pins

Yahoo group: regenrx (2016 — 2017)

The 0C3 has an internal connection from pin 3 to pin 7 with no function inside the tube.
The datasheet says its a jumper to use in case the tube is removed. How would you do anything with those pins
in a circuit?

26507. Walmart wire home brew choke is 1.5mH

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-28 04:38:07 UTC
From: Rob
Topic: 26507 Message: 26507

The mission was to hand wind a 2H power supply choke.
The experiment started with just winging it by stacking steel plates in a
2 inch toroid shape then wind as much wire as would fit in one layer.
Since the wire comes in 4 foot spools I figured I would make taps.
I chose 22 gauge wire because I thought a thinner wire would burn up
like a fuse.
Perhaps that was a bad idea because the result was definitely 1.5 mH
which is a
thousand times smaller than the desired result of 2H.

http://www.learnmorsecode.com/regenx/choke/index.html

But it was a good way to determine if $5 of craft wire would make an
inductor.

How thin is the wire inside a real 2H choke?

http://www.learnmorsecode.com/regenx/choke/2hchoke.jpg

Topic: 26507 Message: 26508

It depends.

Toroids aren't as tolerant of DC current. Most chokes are made of an EI core with a thin layer of insulating material between the E and I sections. This lets the core tolerate a DC current without losing its magnetic ability.

You could build a small choke using 30g wire (or smaller) and reach 2H quite easily. The thin wire will also heat up with a low DC current, meaning you'll lose power and endanger the wire. Find out what current is the maximum for your gauge of wire as used in power transmission. Then use 50-75% of that value.

If your choke measures 2H on an LC meter, it will display less inductance after being used in a circuit. Even with the "air" gap, DC current is going to weaken the magnetic power of the core. Shoot for a higher value so you can be sure to have some wiggle room.

22g craft wire isn't a bad choice for inductors, just not ones with iron cores that might heat up 60-80 degrees.

You'll soon learn why filter chokes are somewhat popular with tube circuits but hardly such with transistor circuits. If you want to try again, smash a cheap DC power brick and steal laminations and wire from the transformer.

Rob wrote:

> How thin is the wire inside a real 2H choke?

Based on Ed's suggestion that your choke's operating current should be no more than 50% to 75% of the current-handling capability of the wire, you could make an educated guess about this by finding the current spec for a given choke and then doing a little arithmetic in consultation with a "copper wire table" that lists current capacity v wire gauge.

There's a reason why high-inductance filter chokes capable of hundreds of mA of operating current are big, heavy, and expensive. :-)

Well, inductance is proportional to turns squared, so; L = k n? where k
is a constant for that core configuration. 2 Hy. requires 4385 turns.

As noted, for a filter choke you need an air gap to resist saturation,
so a toroidal core is not recommended.

Wire ampacity is related to heat loss, and the free air rating is much
higher than when insulated or in a transformer or choke coil. Your 22
AWG wire is probably good for an Amp or two.

Thank you for all the details.
The goal was to determine if a power ripple choke could be added to the caveman science home brew list...
http://www.learnmorsecode.com/regen/index.html

Note my construction method was to alternate where the gap in the strip of metal was in the toroid:
http://www.learnmorsecode.com/regenx/choke/choke01.jpg
and
each strip of metal is wrapped with KAPTON tape
and is definitely insulated from each layer.... lamination.

I thought toroid transformers were harder to wind and that was why EI lamination was the age old standard.
A core bobbin could be wound on a lathe then installed in the EI laminations.

If you want to make a toroid, you need to make it mostly iron laminates. Say you get large, "o" shaped pieces of iron. Varnish them and glue them together somehow (dipping the whole mess in varnish should work). Then take a saw or angle grinder and cut a single gap in the ring of iron laminations. This is your air gap. Put a non conductive material in here (phenolic would be pretty good. Don't use plastic in case your inductor heats up.) The important part is that, while you cement the insulating material into the gap, you need to clamp the choke so there is pressure on the gap. This will affect the magnetism in the core.

The wire current ratings are the current at which a wire, in a bundle of like wires, heats up to a certain temperature. You don't want the choke to heat up much, so I suggested 50-75% of current rating to keep it cool. After it's wound, dip it in a pot of varnish two or three times to prevent intrusion of moisture and insects. The thing will last longer this way.

Another thing...scramble winding the wires will result in a lower inductance than if you lay the wire side by side in neat rows. This is unwanted at RF but we're working at DC now.

I think winding your own choke would be rather time consuming, with unpredictable results, unless you're a young guy with nothing else to do. There are plenty of chokes on the market, not real cheap but reliable. I've also used small fluorescent lamp ballasts with some success. Don't spend all your time winding chokes, and get down to building your radio. It's more fun.

Leonard

Don't. If you wanted a coil for 2 MHZ, scramble winding would make more sense. To remove low frequency signals from your DC, wind the wire in nice even layers. That will allow more inductance and let you get more wire in the tiny little core window.

I'm confused by this statement:

Should it not be feasible to use the primary winding of a
mains or audio output transformer? If so, what kind of
transformer would perform better than a chunky resistor?

An SE audio transformer should work well, as they are gapped for primary current. A power transformer would need to be modified to tolerate such current. The secondary, left open, would pose no problem but would take up room that could be used for more primary wire.

You could connect primary & secondary in series (properly phased) for a little more inductance, but not much DC handling ability.

An SE audio transformer should work well, as they are gapped for primary current. A power transformer would need to be modified to tolerate such current. The secondary, left open, would pose no problem but would take up room that could be used for more primary wire.

26520. 1.5mH scramble or not scramble ... SINGLE ENDED AUDIO transformer

Yahoo group: regenrx (2016 — 2017)

From: Rob
Topic: 26507 Message: 26520

Very interesting discussion here.
This is a single ended audio transformer from tubesandmore.com

....and it shows that the primary is good for 6V6,6AQ5/A plate voltage.....
so I figure it would be happy for power supply ripple smoothing to those
same tubes :
cost $14
https://www.tubesandmore.com/products/P-T31

noting that a real 1.5 H choke costs $15
https://www.tubesandmore.com/products/P-T156R

so if you want the real thing its pretty much nearly the same cost
BUT
IF you were not buying chokes and just building with on hand parts......
and I do have that audio transformer in my parts stash.......
it was good to learn that transformer COULD be used to build the power
supply ripple filter.

26521. winding your own choke would be rather time consuming

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-29 02:32:59 UTC
From: Rob
Topic: 26507 Message: 26521

I'm not a young man.
But I am VP of the local radio club so as the staff tinkerer I get to play like Edison and Tesla.
This particular toroid choke fail just showed how to NOT make a 2H choke.
But it definitely did show how to make a 1.5mH choke.

We had a bonfire a week ago.
I noticed the charcoal left in the fire pit yesterday....so... just for giggles I ground up some of that charcoal in a
coffee bean grinder. It made an extremely fine black dust.
So now I am contemplating what goop to mix that dust with to make a resistor.
AND
I am contemplating how to bag this carbon dust to make a telephone
...old time telephone.. microphone.

15 years ago......I did a Mr Wizard type of "Science of Radio" show at the Franklin Institute Science Museum on Friday
nights for two years. I did six 45 minute shows from 6PM until midnight for 800 kids that
slept on the floor....a gig called CAMP IN. It was one heck of show. I also did it on the road for schools and scouts.

I would always show and tell all modes of ham operation from spark gap to SSTV and often parents would say this
is a rich man's hobby.
And in tough times..... young parents didn't have a lot of spare cash to blow on a hobby.
So I made sure I always did show and tell home brew QRP rigs and the real caveman science
crystal radios..... just to show them that a handful of parts, not real expensive parts, could get you started in the hobby of electronics and ham radio.

So when I go down this path of tinkering with making ANY component from scratch......
its not that I need to replicate something from 1930.
I am just trying to learn how to make something from scratch so I can teach the kids..and parents...
that there is more to this hobby of electronics than buying penny transistors from China.
There is an actual science of creating working components ....
yourself.... with readily available materials.

I have on hand right now every component required to build every transistor radio in a few hundred publications.....

ranging from the simplest germanium diode with a germanium PNP circuit
or AM radio TA7642 IC or 7.16resonator based regens... to any flavor of
NE602 rigs...

BUT
I'm not building radios to sell. I wanted to learn HOW they work
first.... the kit the components for scouts.
So winding a 2H choke to flatten ripple into an 0C3 103 volt regulator tube
has really been very educational for me.
Definitely learning more than the paint by numbers transistors circuits
I built over the years.

Rob, Leonard, et. al - -

Get yourself a copy of Alfred P Morgan's "The Boy Electrician", wherein he shows you how to build carbon microphones, dry cell and wet cell batteries, a small dynamo to charge them, telegraph keys and sounders, meters, a crystal set receiver (of course), a regenerative receiver, rheostats, rotary switches, transformers, motors, capacitors, basic test equipment, and all sorts of other electrical and electronic parts.

First written in 1915, and updated frequently, the book is long out of print, but used copies are readily available.

An extremely valuable resource, written for the young person with a set of basic hand tools, some imagination, and no money. I have built several of projects and all of them worked, some better than others. You won't be sorry to have this book, and I credit this book for sparking my interest in ham radio and electronics.

Morgan also has several other books of a similar vein. The newer books have titles like "The Boy's First (followed by the Second, Third, Fourth, etc.) Book of Radio and Electronics",

Since the early edition(s) are out of copyright, legal scans have begun
to appear: www.tayloredge.com/museum/museum/TheBoyElectrician.pdf being
one example.

Morgan's books were important to a lot of us, I imagine. I checked out
the one copy available at my neighborhood library so often that the
librarians used to tease me about not reading anything else.

--Cheers,
Tom

Rob, that puts a whole different light on the subject. Lindsay put out a set of booklets entitled "The Impoverished Radio Experimenter." Ben Tongue (of Blonder-Tongue) put out dozens of articles on crystal sets, some quite detailed. If you can find any of the Alfred P. Morgan books (The Boy Electrician for example) you'll find articles on winding transformers and making many of the components for your radios. One major problem with the old DIY books is that many of the materials required are no longer available or are considered toxic or hazardous. Anyhow, good luck with your projects.

Leonard

From: Tom Lee
Topic: 26507 Message: 26525

Hi Rob,

Wonderful that you shared your skills with a generation of youngsters.
I'm sure that you inspired quite a few kids!

As to what goop might be useful for your bonfire ash experiments, I have
used Purell as a carrier for graphite dust to make conductive paint
(poor man's aquadag) to repair keyboards and such. It might be worth
including as a candidate for your experiments.

--Cheers,
Tom

26526. winding your own choke would be rather time consuming BOY

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-29 11:07:40 UTC
From: Rob
Topic: 26507 Message: 26526

YES... I love that book BOY ELECTRICIAN
but
the online PDF.. which I do have from
http://www.tayloredge.com/museum/museum/TheBoyElectrician.pdf

Is too light to read and if I enhance the image I lose the detail in the
drawings...
see here:
http://www.learnmorsecode.com/boy/index.html

It there any way to get a this to be readable...both text and images?

And.....
definitely a bitch to find the toxic raw materials to build the Lindsey
books
archive of batteries.

I do have some of the Impoverished Radio experimenter.....
and some Ben Tongue.

Arnie said there was a Ben Tongue QUADRUPLER DIODE radio in SPRAT but we
can't seem
to find that schematic. Anyone got that circuit to share?

==========
Rob, that puts a whole different light on the subject. Lindsay put out a
set
of booklets entitled "The Impoverished Radio Experimenter." Ben Tongue (of
Blonder-Tongue) put out dozens of articles on crystal sets, some quite
detailed. If you can find any of the Alfred P. Morgan books (The Boy
Electrician for example) you'll find articles on winding transformers and
making many of the components for your radios. One major problem with the
old DIY books is that many of the materials required are no longer
available
or are considered toxic or hazardous. Anyhow, good luck with your projects.

Leonard

26528. Purell mixed with charcoal dust makes India ink

Yahoo group: regenrx (2016 — 2017)
Date: 2016-05-29 12:28:16 UTC
From: Rob
Topic: 26507 Message: 26528

Purell?
I had not thought of that.
But that reminds me of the India ink grid leak experiments.

There is a project on the web where a guy mixes graphite.... the kind
you lubricate
lock tumblers......
with liquid tape....
black glue that electricians use instead of black tape.....
and he builds LED art work light fixtures and other electronics using
goop made resistors.

Teaching the kids to do make something instead of buy something does a
lot more than
make a toy to play with.

It teaches the kids how to think to solve real world problems without
hiring a consultant.

My son sat next to me, with a welding mask, when I patched the leaking
60 year old oil
furnace with a stick welder.
I let him draw arcs and weld metal plates when he was 12 years old.
Two years later he was taking parts from two broken down junk bicycles
and building
one good bike.
He asked for some help because he could not align the forward derailer
properly.
I saw that the frame was cut just above the rear axle and declared that
it would never work
because when the kid sits on the bike it would flex.... and asked WHY is
the frame cut.
He said they could not figure out how to break the chain to swap bikes
so he CUT the frame.
I then asked with what tool did he cut the frame?
He replied "your bolt cutter".
I was surprised.
HUH?
bolt cutters!?
and saw the second bike frame ..the chain source bike.. had a chewed up
frame also.
and then I saw the bolt cutter..... jaws all shattered with chunks missing.

OK.... so.... then I asked the kid what was he thinking? What good is a
broken frame
bike?

To which my son replied "I figured you would weld it back together for me."
Yep. Thats my son. Taught him that Dad can make or fix anything.
10 minutes later that bike was rolling down the street.

And whats he do now..20 years later?

He delivers and builds stages for the rock concerts that are held inside
the NASCAR infield
and after the band plays...the stage MUST be disassembled before the
race starts
so the view is not blocked.

So yea..... teach the kids whatever you can..... technical, math,
machine shop skills.....
snowboarding..... whatever you can.....
because one day the PLAYSTATION or NINTENDO or whatever internet
connected NETFLIX
crap we have been feeding these kids for their first 15 years of life is
going to backfire
and the best job they will get will be honing their skills saying "DO
YOU WANT FRIES WITH THAT?"....
IF they can pass a drug test.

My download is slightly fuzzy and greyish, but perfectly readable.
Maybe tinkering with pdf reader settings will enhance readability.

Great stuff! Maybe I am older than I thought...

Michael

I have a book you would probably be interested in. It's called "Voice of the Crystal" and it details making components of radios down to DIY variable capacitors, roller inductors, high impedance headphones, and crystal detectors. Send me an email off list if you want it.

Rob,

<forehead slap> Thanks a lot for mentioning graphite lube. I'll have to get some -- it would certainly be a lot less work than grinding up graphite blocks!

--Cheers,
Tom

26535. vintage 2H choke might be 36 gauge wire

Topic: 26507 Message: 26535

vintage 2H choke might be 36 gauge wire.

Now I can see why the last component in the AC ripple filter chain would
be a 1/4 watt resistor to act like a fuse.

A fuse resistor, or even an actual fuse, is a good idea especially now that most power supplies use silicon diodes capable of relatively high currents.

Fuse resistors were not used in the heyday of vacuum tubes, likely because the relatively high impedance of thermionic rectifiers tended to make the rectifier tube(s) pay the price of an extended short circuit. Look at power supply after power supply in yesteryear's tube-based articles and ham handbooks and you won't see one in the schematic.

Another aspect not superfically apparent in yesteryear's schematics was that high values of filter capacitance were more difficult to come by than high(er) inductance chokes. (Commonly we see filter C with values in relatively low multiples of 2 (2, 4, 8, 16 uF, with oil-filled capacitors were standard before electrolytics became sufficient reliable). Getting sufficient filtering with such low C mean you needed high L.

Beginning one's power-supply filter with a choke of at least the _critical inductance_--that's a term of art that you can research--protected one's rectifier tubes by limiting the peak current the rectifiers had to handle. Nowadays, when for pennies you can by high-voltage rectifier capable of _amperes_ of forward current, building in that much "iron" is less necessary, as relatively cheap high-value filter C can offset the absence of L.

Best regards,

Dave
amateur radio W9BRD

Getting sufficient filtering with such low C mean you needed high L.”

I’m struggling with these early design decisions as I rebuild an old James Millen HV supply from the late 1940s. In searching for replacement oil caps, I discovered that as either capacitance or the voltage rating of the cap doubles, so do the physical HxWxD dimensions – at least for these early oil types.

In this particular supply, a Millen 90281, two oil caps are contained within a small compartment under the chassis and form the input to a C-L-C-L-C filter design. I’m now going on my third set of caps. After a few days, the preceding caps failed with dead shorts.

Due to cabinet space contains, Millen used the two input caps in parallel. There’s simply not enough cabinet space for 1.5KV oil caps of the same capacity. Adding to the search difficulty is that GE and other oil cap manufactures used several different mounting styles. Apart from age, I can only reason that failure occurs because the no-load peak rectifier voltage is charging the input caps to slightly over the 1KV WVDC cap limit. My mains voltage runs ~ 127 VAC. In the late ‘40s, I suspect normal line voltage ran closer to 115 VAC. So, unless I reduce line voltage with a Variac or similar autotransformer device, I may forever be stuck in this situation. It’s probably a good idea anyway.

Since the two input caps cannot be seen with the bottom cover in place, I’ve been tempted to use a pair of 2KV/2uF Polypropylene film caps. While quite large, they do fit in the compartment. Seems to me the ESR of these film caps should be close to that of oil caps. Any reason why not?

BTW, back in the late ‘20s, Millen authored a multi-part series of articles in QST that dissect the operation of multi-stage PS filters. The first article is titled “The First Filter Condenser,” and appears on p. 33 of the Sept., 1927 issue. This series represents an important milestone in power supply development as regen gear was transitioning from battery operation to AC-mains supplies.

In my visit to the local goodwill I noticed a lot of cell phone chargers, many of which have small transformers inside. I had a thought. Can you connect two transformers together so that identical voltage primaries are connected to get an isolated 110 volt ac? Might help with small tube type regenerative radios.

Absolutely right amigo !
Back to back connection of identical transformers provides
excellent power line isolation.
If the secondary windings can handle enough current and are
providing 12 volts , then you end up with the best of two worlds...
Use the 12 volts at the link between the two transfomers to
provide filament voltage to your vacuum tube radio (need to use
a 12 volts filament tube, or two 6 volts filament tubes that take
the same current connected in series...
At the ¨ other side ¨ of the second transformer you will have,
for example about 120 volts AC, that can be properly rectified
and used .
BUT, about the cellphone chargers... BE AWARE, that most of them
if not all use SWITCHED MODE POWER SUPPLIES, that are
transformerless circuits...
OLD, ancient walwarts for powering 5, 6 , 9 or 12 volts solid state
devices did used transformers , conventional bridge o two diodes
rectifiers and a large capacity electrolytic...

Short answer: YES

Some things to consider. (SRI if this is repeating other posts - I've read none)

The input transformer must be able to deliver (at minimum) the *total* power consumed by *all* loads, then (as a rule of thumb) multiply by 1.1 to account for losses.

The "step up" transformer will lose some efficiency (hooked up backward) but will work nicely. Again the size is determined by the power consumed at its output plus losses.

FWIW: I would reccommend using 1N4007 diodes, since the entire line 1N400X are all lower grades of this part, all are cheap! Added plus, the 1N4007 makes a nice poor man's varicap.

Finally, a full wave rectifier circuit would allow reduction of the size of the filter cap by 1/2. CAPS are expensive compared to diodes, but check the junk box first. :-)

You should see about 160-170V from this circuit under no load.

Hope this helps.

About the back to back transformers utility power supply

I use 1N4007 recycled from CFL circuit boards.... at zero cost !
Also use high capacitance electrolytics recycled from computer
power supplies... 220 mfd, 330 mfd and even 470 mfd at no less
than 250 or 350 volts provided great filtering !
Using a 10 Henry choke input filter is also a great idea....
The 170 volts or so output will provide enough voltage to
strike a VR105 or VR75 gaseous discharge voltage regulator tube
that is a worthwhile addition to the utility power supply.
In a more recent version, I wound a 6 volts winding on the
second transformer to make a 1 amp regulated 9 volts power supply
that can be second step regulated to 6 volts to feed the filaments
of the regenerative detector tube...
Also useful to feed the filament of the first audio amplifier stage
helping to reduce hum...
Follow my advice and build the power supply on a separate chassis !!!

I've been waiting for someone to bring up the subject of efficiency with back to back transformers. I would still like to know why 170 volts obtained this way is any less dangerous than 170 (properly fused) obtained right off the power line. I use IEC connectors with all my projects, which require a 3 wire grounded power cable. Of course, this may not work for people living in areas where the power system is not grounded or polarized.

The transformer (by design) provides isolation from the "outside world". The high voltage is still dangerous, but its circuit is self contained and isolated from external wiring. On the contrary, if you grab the 120VAC line directly (or even through a DC circuit) then touch any object attached to earth, you likely will be shocked.

Not so with isolation from the line. The "secondary" circuits do not provide safety other than isolation from the line.

I think the bottom line here is, don't grab the 12- VAC line, ever. I use an isolation transformer with many of my commercial receivers for reduction of line noise, and so I can select either line ground or earth ground. I also noticed that it greatly reduced the hum in my R-649A (an AC/DC receiver) Other reasons for using transformerless supplies, they take less space, and I'm running out of power transformers. I have built several separate unversal power supplies, one with a built in audio amp and electronic circuit breakers, but I prefer to have everything on one chassis.

Subject: Re: [regenrx] B+ supply question

The transformer (by design) provides isolation from the "outside world". The high voltage is still dangerous, but its circuit is self contained and isolated from external wiring. On the contrary, if you grab the 120VAC line directly (or even through a DC circuit) then touch any object attached to earth, you likely will be shocked.

Not so with isolation from the line. The "secondary" circuits do not provide safety other than isolation from the line.

Short answer: YES

Some things to consider. (SRI if this is repeating other posts - I've read none)

The input transformer must be able to deliver (at minimum) the *total* power consumed by *all* loads, then (as a rule of thumb) multiply by 1.1 to account for losses.

The "step up" transformer will lose some efficiency (hooked up backward) but will work nicely. Again the size is determined by the power consumed at its output plus losses.

FWIW: I would reccommend using 1N4007 diodes, since the entire line 1N400X are all lower grades of this part, all are cheap! Added plus, the 1N4007 makes a nice poor man's varicap.

Finally, a full wave rectifier circuit would allow reduction of the size of the filter cap by 1/2. CAPS are expensive compared to diodes, but check the junk box first. :-)

You should see about 160-170V from this circuit under no load.

Hope this helps.

My computer is short changing the numbers. Here's my comments again.

I think the bottom line here is, don't grab the 120 VAC line, ever. I use an isolation transformer with many of my commercial receivers for reduction of line noise, and so I can select either line ground or earth ground. I also noticed that it greatly reduced the hum in my R-649A (an AC/DC receiver) Other reasons for using transformerless supplies, they take less space, and I'm running out of power transformers. I have built several separate unversal power supplies, one with a built in audio amp and electronic circuit breakers, but I prefer to have everything on one chassis.

Cool.

The trick on winding toroids is to use a shuttle to carry the wire through the core and around it.

The binder of choice for "Carbon Composition Resistors" was some type of clay, which had the graphite mixed into it, and then fired, usually with electrodes embedded in the ends. That'll give you a start for some searches.

For the Carbon microphone, I believe that the graphite was just included loosely between the microphone frame and the diaphragm.

Don't forget about waxed paper capacitors. The old timers used coat hangers for
the core of some transformers. I'd probably recommend a pass on the electrolytic
rectifiers (aka "slop jar rectifiers", for reasons which will become apparent if you try
to make one).

Heck, I've even made a diode from a partially burned out, dual filament, automotive
brake light bulb.

For more radical stuff, see "The Voice of the Crystal", and "Instruments of Amplification".

You can fabricate crystal radio diodes out of natural mineral Galena or Iron Pyrite.
For those desperate (stupid?) enough, you can even synthesize Galena from molten
Lead and powdered Flowers of Sulfur (But, this is strictly an outdoor activity. Wear
all appropriate safety gear, and keep things SMALL!). For that matter, there are
literally hundreds of natural materials which will function as a diode in a crystal radio.

http://pw1.netcom.com/~wa4qal/nontrad.txt

Greenleaf Whittier Pickard (q.v.) tested something like 33,000 materials or combinations
of
materials back in the early days of radio.

I like to use a variable speed electric drill to rotate the core, while
feeding magnet wire onto it, to wind a coil with. Make sure the

person running the drill is VERY trustworthy, and remember that magnet wire can cut you like a knife.

I gather that you want the supply to look as it did in its heyday. Otherwise you'd use modern electrolytic caps--seriesed and with equalizing resistors as necessary--and be done with it.

I strongly recommend avoiding vintage oil-filled capacitors for the reason that the oil in them almost certainly includes polychlorinated biphenyls (PCBs) as fireproofing agents. Capacitors labeled to trumpet such elixirs as Dykanol and Pyranol are examples; more about this problem in the document available at
https://www.cdph.ca.gov/programs/hesis/Documents/pcbs.pdf
https://www.cdph.ca.gov/programs/hesis/Documents/pcbs.pdf . For example, if you've ever encountered oil-cap oil that smells like mothballs, you have likely encountered PCBs.

That such old caps contain hazardous oil also means that a common technique of those seeking to reproduce yesteryear's look can't safely adopt the dodge of draining the case of a given old oil cap, removing its innards and replacing them with modernity. So what I recommend that you obtain/fashion capacitor cans that look reasonably like the original oil-filled jobs and mounting an equivalent network of modern series/equalized electrolytic parts within them.

And while you're at it, make sure that the peak/surge voltage applied to a given modern equivalent stack doesn't exceed 2/3 to 3/4 the working voltage of the stack. If a line voltage change from 110 to 125 can blow power-supply parts, that's a poorly designed supply.

Best regards,

Dave

Yes, but three things:

1 Use a full-wave rectifier (four diodes in a bridge) instead of a half-wave rectifier. A half-wave rectifier doesn't use the full current capability of its driving transformer to provide useful output _and_ needlessly heats the transformer because it causes a net dc flow through the transformer secondary.

2 Don't use 1N4001 rectifier diodes, even in a bridge, for a 170-V-ish supply. Use 1N4005s or higher-n 1N400n parts or their equivalents. (If you're ordering some, get 1N4007s, as their 1-kV PIV rating will make them hard to pop [from overvoltage] in 170-V-ish supplies.)

What's "PIV"? Do go read up on the voltages and currents that power-supply rectifiers must withstand in various rectifier/filter configurations. And then go look at a spec sheet for the 1N400n-series diodes to get an idea of what different members of the series can take. (The lower the n in 1N400n, the lower the PIV rating of the diode. Fun fact: And 1N4007s can also be used as PIN diodes for RF switching....)

3 Powering heaters _and_ the second transformer from the first transformer means that you have to take both output paths into consideration in determining how much heater power and dc-supply power you can expect to get without overloading the first transformer.

Best regards,

Dave

That's two separate questions.

Here's how this issue works for me:

1 The value of transformer isolation is isolation from hot _and_ neutral on the line and current-limiting (in the case of a secondary-side fault) by means of the impedance of the transformer.

Isolation from hot _and neutral_ matters because there are all sorts of line-side faults, including wiring by yahoos that transposes hot and neutral and including high resistance in, or outright failure of, the neutral connection. I have personal experience with failure of the neutral.

And of course transformers can also step voltages up and down as they provide that isolation. Only in this special 1:1 voltage case does transformerless operation suggest itself. (Nope, voltage multiplication does not change my position. Only an isolation transformer or transformers protect me from calamity and idiocy on the line side, and idiocy on my side.)

2 Once the life-and-property-protecting value of isolation is established, questions of efficiency are moot. (And good-quality transformers make it more so. Have you _ever_ seen catalog listings for transformers convey their efficiency? No, because for properly applied good-quality transformers it's high. We're only powering up little regenerative receivers here!)

If you have or can buy an actual isolation transformer, fine; if not, two transformers back to back will be only slightly less efficient, especially if one is sufficiently mentally alert enough to avoid using half-wave rectification--which _very noticeably_ heats the transformer compared to the full-wave-bridge case--on the output side.

Out,

Dave

>”I gather that you want the supply to look as it did in its heyday. Otherwise you'd use modern electrolytic caps--seriesed and with equalizing resistors as necessary--and be done with it.”

That was my first thought, but couldn’t bring myself to using ‘lytics in this instance. Although, if it was the last available port in a storm…

While working with the older oil caps, I’ve been using surgical gloves to keep the PCB-infested oil from making skin contact. In a prior working life, our company had to dispose of several hundred pounds of GE Pyranol-branded caps. Removal was very expensive and was facilitated though a GE-licensed contractor. Makes me wonder how many OT ops thought nothing about coming into contact with capacitor and transformer oil. They didn’t fear exposed HV so why oil?

Several sets of caps are due to arrive next week and I’ll likely make a final decision at that time. Of course, the new oil caps don’t contain PCBs but they may have to be kludged into the compartment.

Excellent point about selecting caps with some WVDC headroom. It would be an interesting discussion with James Millen since he likely contributed to the electrical, as well as mechanical PS design.

OK, it's time to bring up the PCB "scare" again.

Some years ago, between 1965 and 1975, I was a technician on the Alaska "White Alice" OTH troposcatter communications system. Part of our job was to routinely test the transformer oil in the transformers that powered the 10 KW and 50 KW klystron amplifiers. This oil was known by the trade name "Askarel", and was of course a PCB (polychlorinated biphenyl) compound.

It was not uncommon for a tech to have his or her hands in this oil up to their elbows during this process.

I have never heard of an instance where this exposure resulted in ANY sort of illness or health issue.

Now, I am not advocating that anyone go out and have a hot steaming cup of the stuff, and a bit of caution is prudent, but I personally think that the PCB problem is overblown to an incredible degree. And "incredible" is the right word (meaning not credible) - a person would have to literally drink the stuff by the gallon to get the same exposure as was fed to lab rats during the cancer tests. Hell's bells, drinking too much water can kill you! That is indeed true.

So, if you get a few drops of a PCB containing product on your hands, and you wash wherever there is / was skin contact, you aren't going to die later this afternoon, or even next year, for that matter.

It makes for a great "scare" to make people afraid of things though.

All true. Askarel was invented to replace oil in transformers where the possibility of burning oil was unacceptable, such as in mines, inside buildings. chemical plants, etc. It was significantly more expensive than oil and was not used frivolously. It's only virtue is it will not support combustion. Absorb some Askarel/oil on a cotton swab, and if it burns it's not PCB. I think it's not all that common. It has a higher dielectric constant than oil, so it "could" advantageously be used in capacitors to get more capacitance in the can, but there is the cost factor... As noted, it smells funny, I remember an acrid smell in transformers, which clears your sinuses.

People working at GE were in it to their elbows and they are very healthy. If you don't ingest it or pour it in an open wound nothing will happen.

You don’t need to council me. I’m going to send money to someone overseas with no friends, associates, or relatives in his own country to lean on?

I advised him in that sorry instance, maybe best to make a new life in Istanbul.

I tried to phone the KRC but no ans; might try tomorrow.

I also forwarded to a U.K. magazine, Radiouser, and advised his website host.

And blocked the email sender.

From: Leonard Meek
Topic: 26538 Message: 26560

I hate to belabor the subject, but I would think that anyone working with even moderate power transmitters would be exposed to more danger than with a little AC/DC radio. I don't personally know of anyone getting killed in either case, but there are plenty of old stories about taking a radio into the bath tub. I don't sweat the wiring in my shop because I did it myself, so I know it's correct. Additionally, I have several isolation xfmrs. One is installed in my bench with a 5A Variac and a lamp bank for use with questionable loads. One rated 15KVA powers most of my commercial receivers and helps to reduce line noise. I think a lot of guys would agree with me, but unfortunately they're no longer with us.

> I would still like to know why 170 volts obtained this way is any less dangerous than 170 (properly
> fused) obtained right off the power line.

That's two separate questions.

Here's how this issue works for me:

1 The value of transformer isolation is isolation from hot _and_ neutral on the line and current-limiting (in the case of a secondary-side fault) by means of the impedance of the transformer.

Isolation from hot _and neutral_ matters because there are all sorts of line-side faults, including wiring by yahoos that transposes hot and neutral and including high resistance in, or outright failure of, the neutral connection. I have personal experience with failure of the neutral.

And of course transformers can also step voltages up and down as they provide that isolation. Only in this special 1:1 voltage case does transformerless operation suggest itself. (Nope, voltage multiplication does not change my position. Only an isolation transformer or transformers protect me from calamity and idiocy on the line side, and idiocy on my side.)

2 Once the life-and-property-protecting value of isolation is established, questions of efficiency are moot. (And good-quality transformers make it more so. Have you _ever_ seen catalog listings for transformers convey their efficiency? No, because for properly

applied good-quality transformers it's high. We're only powering up little regenerative receivers here!)

If you have or can buy an actual isolation transformer, fine; if not, two transformers back to back will be only slightly less efficient, especially if one is sufficiently mentally alert enough to avoid using half-wave rectification--which _very noticeably_ heats the transformer compared to the full-wave-bridge case--on the output side.

Out,

I think the high-dosage tests were not so much to predict inevitability of getting cancer as predicting incidence of cancer at lower doses.
Of course PCB is not so skin-permeable as toluene or highly refined petrochemicals and some drugs, which will go thru the skin barrier.
Yes, your chances of any problems from PCB - or your future children's problems - arise from somehow ingesting PCB, which is probably unlikely.
There are some sites in the USA where rivers or channels are still so polluted that the fauna are either gone or have serious problems.
I can think of, right off, Duwamish River in Seattle; Gowanus Canal, New York; Columbia or Willamette River, Oregon, on their last sections.
I recall seeing a photo in the Portland, Oregon newspaper of an immigrant fishing, i think in the port area, a few yards away from a big billboard warning that fish from the area were unsafe to eat.

Back in the early 1980s i had a large bunch of high voltage, transmitter type PCB oil caps. I didn't need them, and i had just read something about the danger of PCBs, and i was all unnecessarily alarmed and worked up.
I called some relevant authority and was told i could have the caps packed in 50 gallon drums and trucked to a haz waste site, at my own expense, of course. Now it's a lot easier to dispose of haz stuff. Just as well; landfills do leak, so the easiest route is not really the best for our home planet. But i'm a whole lot less concerned about the PCB caps i still have.

Going thru paper here, i saw an early article on low-voltage tube radio.
"World Radio" magazine for May 30, 1931 - published weekly then ! -

has an article on pg 10 - "A One Tube Set with 15-550 Meter Band Selector
Switch". The A batt is 3 volts and the B batt 7.5 volt, so the stacked

B+ is 10.5 volts. The circuit is also unusual in use of no plug in coils;
uses one coil with 4 taps; unused section is grounded out.

I am kind of puzzled by this statement: "The reception on short waves is
good, and that on broadcast waves is only fair. " I would have expected

it to be other way around!

Oh ☐ i noticed something. The circuit is drawn wrong. In the magazine schematic, the var cap taps down on the coil ☐ which would only progressively lessen

the tuning range of the capacitor. The capacitor should go to the top of the coil and the taps should go to the bottom of the coil thru a shorting 4-step switch.

The circuit has a grid leak, of course, but by returning the grid to the +3 of the A battery, there is also (½ x 2) filament voltage + 1 volt fil resistor drop =

+2 volts bias on the grid in addition (or opposition) to grid leak bias.

I would avoid shorting turns of the tuning coil. Shorted turns
reduce Q. Instead, the grid-leak could be detached from the top end of
the coil and connected to the switch wiper.

One of my first ever regens worked on 22v HT. What more recent
tubes would work on 10.5 or similar B+ ?

There was an article i saw in Radio News from around 1954 that used submini tube and one transistor. As i recall, the transistor took off from the tube cathode-follower
style. The text said the tube would regenerate down to something like 3 volts. The actual B+ and transistor supply was a 7.5 volt battery.
Oh, i just found it in my articles list:

Tube and Transistor Radio (regenerative) 6088 submini as triode; single transistor audio; 7.5 volt supply
Sep 55 p42 Radio-Electronics magazine; audio from triode cathode ckt

Then there's also this article:

A Most Unusual Oscillator (Hubbard osc, B+ less) R&TVN May 1955 52

The 'Hubbard oscillator' uses no B+; electrons are supplied only from the filament, not B+ stacked from the filament supply; in fact, the filament circuit is not connected
to the other tube elements, it's isolated, except for electrons that boil off. Some German website i saw seemed to rediscover this circuit, but this is the first instance of it
i have seen, and Mr. Hubbard deserves his credit. The circuit does need a tube with a hefty filament that runs a good bit of power, power tubes like 6V6 or 50C5.
Those articles are probably accessible via americanradiohistory.com

re the coil tap issue: this question seems to reappear perennially. Some time back i quoted this test result from QST:

Measured Q data of simulated amplifier tank inductor, tapped open or shorted comparison QST Feb 2011 62

As i recall, as shown by a chart of actual Q readings, it just did not make a substantial difference. I'm open to other opinions though

>☐So, if you get a few drops of a PCB containing product on your hands, and you wash wherever there is / was skin contact, you aren't going to die later this afternoon, or even next year, for that matter.☐

Except for those persons genetically predisposed to even a small intake of PCB whether by ingestion or skin absorption. Absent a comprehensive DNA screening, we don☐t know who among us can bath in PCBs without ill-effect, while cancer calls for the fella☐ who☐s DNA isn☐t nearly as resilient to exposure. Probably all of us are more or less predisposed to any number of cancer-causing agents including exposure to chemical carcinogens, UV, nicotine, the air, and soil. At some point, and through some method, researchers concluded that PCBs posed an elevated risk to humans.

>☐It makes for a great "scare" to make people afraid of things though.☐

It would be naïve to think that the 1980s PCB scare was the result of an outpouring of compassionate concern by state and federal health agencies. Any time big money is involved and freely available to be had, well

Paul, W9AC

On 6/1/2016 4:16 AM, 'Paul Christensen' w9ac@... <mailto:w9ac@...> [regenrx] wrote:

>☐I gather that you want the supply to look as it did in its heyday. Otherwise you'd use modern electrolytic caps--seriesed and with equalizing resistors as necessary--and be done with it.☐

That was my first thought, but couldn☐t bring myself to using ☐lytics in this instance. Although, if it was the last available port in a storm

While working with the older oil caps, I☐ve been using surgical gloves to keep the PCB-infested oil from making skin contact. In a prior working life, our company had to dispose of several hundred pounds of GE Pyranol-branded caps. Removal was very expensive and was facilitated though a GE-licensed contractor. Makes me wonder how many OT ops thought nothing about coming into contact with capacitor and transformer oil. They didn☐t fear exposed HV so why oil?

Several sets of caps are due to arrive next week and I☐ll likely make a final decision at that time. Of course, the new oil caps don☐t contain PCBs but they may have to be kludged into the compartment.

Excellent point about selecting caps with some WVDC headroom. It would be an interesting discussion with James Millen since he likely contributed to the electrical, as well as mechanical PS design.

Why are we questioning PCBs?

I have attended no less than 3 funerals for people who died at ages 30,
40 and 67 of horrible cancer deaths.
Two of those people smoked and died of lung cancer.

If science says it causes cancer
it probably will kill you so lets not discount the hazards of PCBs.

This discussion started with talking about capacitors that can not be
bought now.

Its easy enough to hand craft antique faux electronic parts:

Rob, the round disks were some kind of red fiberboard I found in my junk box. The #6 dry cells are filled with "C" cells. The large 45V battery is 30 AA cells. The smaller one is five 9V batteries.I'm using them right now to test some submini tubes with numbers that don't cross to anything. Some are proximity fuze tubes, others I suspect are old hearing aid tubes, I'm testing them in actual circuits to see what they'll do.

I dunno guys..... maybe something to this... maybe not.....
the two guys asking for the cards to make faux batteries are

Gary Pewitt

and

Jim Pruitt

Not sure what that means.... but I did play the lottery and won $15 today.

26577. Question on coils

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-03 18:34:35 UTC
From: Leonard Meek
Topic: 26577 Message: 26577

I'm not a scientist but I have dabbled a bit in particle physics and ditch digging. I have a bunch of RF coils that I don't fully understand. The secondary is about 330uH, which is about what you would expect for MW use. The primary is over 7000uH. That's the way they're marked on the little data sheet that comes with them. Is there a simple explanation for this?

Leonard

Together with a 1nF capacitor parallel to 7mH that coils could be used for a 60 kHz second if.

According to the data sheet it's a PC-70-RF coil, and I think it was sold as an antenna coil. I thought maybe it was intended for solid state but the accompanying diagram shows a pentagrid tube.

This is an interesting group, and I hope the members who are passionate about tubes can help me with the Museum https://groups.yahoo.com/neo/groups/RadioModifications/conversations/www.vacuumtubemuseum.org.

There are many collectors and other organizations with various tube-oriented websites and a few with physical collections, but the International Vacuum Tube Museum is the only formal vacuum tube museum organization worldwide. It is a true museum, dedicated to the past, present, and future history of vacuum tubes, and devoted to the collection, study, education, exhibition, research, conservation, interpretation, preservation and documentation of vacuum tubes and vacuum tube artifacts.

It will take quite a while and many projects to build this into a first class Museum. I have made a lot of progress, especially over the past couple of years. With a very little amount of help, I set up the Museum as a 501(c)(3) nonprofit so that all memberships and donations are tax-deductible contributions to the Museum. Over several decades, I collected thousands of tubes and hundreds of tube radios, test instruments and all sorts of other tube-based gear, and dozens of books, magazines, manuals, spec sheets, brochures, catalogs and countless other print literature and documents. I spent my own money to cover more than 90% of all the expenses to get the Museum to this point. I recently snagged a donation for some temporary space and am finishing a nice gallery. You can see photos here http://vacuumtubemuseum.org/new-gallery/. Unfortunately, this only shows a small portion of the tubes and tube-based radios, tube-based test equipment, and other tube gear that is in storage. The Museum needs more space!

Of course the main goal is to preserve the history and showcase “all things vacuum tube” either in the Museum’s collections, or with links with other museums, libraries, corporate galleries, personal collections, etc.

All of this will take years. And help from hundreds of people and organizations. And money. I am counting on help from people who are passionate about tubes and everything based on tubes.

26581. Transceiver build with regen completed

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-06 10:39:09 UTC
From: dulmagedon@...

Attachments: 1 described; binary payloads are missing from this source WARC

I am easily distracted and was by a mention some where of the old Weskit BN-1 transceiver. I decided to build a clone but dint have a 3a5tube and didnt want crystal control on the TX side. I did however look at the schematic to see how they did it. I know some will poo poo the concept however I heard from a couple of fellows who still have theirs from the 1950s and loved them. Usually those with like and thse wthout know why they are no good. Strange concept but that's life it seems. Anyway I decided to design my own using mostly what I had on hand. Once I got it going i made a tube change to an ECC832 /12DW7(Thank you Tubemuseum for the info) which is a dissimilar dual triode. After I got it going I added a audio amp to the regen to help these failing ears. It works quite well. There is no schematic because it is just two indentical hartley osc, one as a transmitter and one with a regen pot and phones. The audio amp is nothing fancy. Typical bean power amp. A half dozen parts and some wire. Resistance coupled. Radio is not hand sensitive and tuning is very comfortable. Tx and RX are single tuned with a dual gang variable cap. RX has a bandspread added for sweeping up and down on freq and Tx has a padder to keep it equal tuning rate to RX. Slugs are set so with bandspread in centre or half way RX and TX are on the same freq. The hartley Regen lends itself to use with a bigger antenna so one antenna s used and switched along with B plus for TX or Rx. It is powered by my shack light duty hb PSU and hum is not an issue. It can hear weak station very well. better then my Dx160 Con receiver. Fun build and fun to run. The finished set is quite a bit different then the BN-1 Weskit but the concept is stolen directly from looking into that little amazing radio. I call mine the DN-1 for Don 1.

Yes.....schematic and coil would be very helpful.

I was surprised by the wire gauge on the coils.
I thought we were supposed to be using thin magnet wire for the coils.

From: Hubert Miller
Topic: 26581 Message: 26584

One clever point about the BN-1 is that the transmit-receive switching is done by simply switching the halves of the 3A5 filament getting current.

The worst downside is the tuning rate. If you are used to maybe 40 kHz per knob turn, the BN-1 is something like 4 MHz per knob turn.

Welcome, Charles. I like working with tubes, but I'm far from being any kind of expert on them. I've accumulted some tubes over the years and now I'm trying to find uses for them. I have a number of submini tubed that I've been experimenting with that have no ID numbers on them or have numbers that don't cross to anything. Some are proximity fuze tubes, others are probably hearing aid tubes. If you go to the RegenRX 2, Files section under Leonardmeek, and look at my Mk.19 schematic, you can see what I'm doing. It would be nice to have a little more data on these tubes.

Leonard

we were supposed

Says who?
I had no schematic. It is a pair of hartleys. I had to draw the circuit from memory when I wrote my license many years ago. I assume you all did too. Coils can be what ever band you wish. For 40M double the freq + approx number of turns. (7 MHZ = 14 turns. I sometimes use 16 just to be sure on small forms but it usually works on any size between 1/2 and 1 1/4")
Using the insulated solid hookup wire for coils gives one automatic perfect spacing. Simple but very effective. I use it when ever I can. The regen works very well.

Well both the main tuning cap and the rec bandspread have 6 to 1 reduction so I can walk all around a signal without losing it stopping where I like it best. I nixed the switiching filaments in favour of switching B + along with the antenna to the antenna coupling links. Either tx link or rx link. .

the schematic of the original BN1 is here.
http://www.nt9k.com/stuff/BN1schematic.gif

Yah, I like the TR switching! I don't see a direct connection from the antenna to the receiver side; I suppose the few pF needed are provided by stray capacitance between the tube halves?

That’s exactly it. Also if i recall from the instructions, the regeneration changed slightly when you tuned the receiver to the transmitter crystal frequency,

so that was a kind of ‘netting’ feature, in a way.

The switched filament idea, i think the designer got from a U.S. Navy aviator rescue walkie talkie WW2.

FOR SALE:

This is a true collectors item if ever there was!
1947 Micromatch SWR / Power Meter as described in QST Magazine for April 1947 Pages 15-20.

Measures SWR, Power Ratio (!) and also Power - forward and reflected in Watts.

Can be used for several different transmission line impedances from 50 to 300 ohms!

There are two SO239 connectors for input / output and associated banana jack / binding posts.

It's hard to tell whether this unit is commercially produced (sure looks like it) or something home brew.
It may even be the exact unit that was built for the article. In any event it comes with documentation.

Pictures and details at:
http://af4k.com/miscpart.htm

Available for $60.00 plus shipping.

Thanks, Charles. Right now I'm just breadboarding circuits and varying circuit values to see what I can get away with. I note that most of the battery operated subminis have 1.25V filaments, but a few filaments are 0.65V. I have literature on proximity fuzes but I haven't found any mention of filament voltage. I took a chance with 1.5V and it seems to work okay, but lights up quite brightly. In my Mk.19 I connected 2 filaments in series across 1.5V and they still work very well.

It's in the RegenRX 2 (overflow) files,. not RegenRX files. I think it's a separate group, formed to handle the overflow from RegenRX. I used 3 submini tubes: one 6088 and two 1268's (?). I don't remember where I got the 1268 number from but I think it was from an article on Sylvania tubes. I bought 100 of them for $1. Couldn't go wrong. I also got 100 diodes (1068) and 100 thyratrons (1168), each for $1. ($3 total)

I have some 6088 and 6418 tubes here.
My interest in them was the non-lethal voltages.

Can the MK19 1268 and 6088 tubes be swapped with 6418 tubes?
Is there a picture of the built radio?

Rob, I'm sure the tubes can be swapped, with maybe a little tweaking of component values. When I built the Mk.19, I just guessed at the values. There are some pics in the Photo section of RegenRx. I used a loop stick so it didn't need an outside antenna.

26599. Re: [regenrx] Current licensing system and learning (long) Transceiver build with regen completed re: solid hookup wire for coils

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-07 07:01:04 UTC
From: kevin asato
Topic: 26599 Message: 26599

The exam is not an end to learning. It is just to make you aware of rules and regs, basic operating procedure, and just touch on some aspects of the hobby. If anything, the licensing reflects the current state of the radio electronics for both the amateur and "professional" fields in which one does not have to know how to completely disassemble a radio and put it back together. I know. I have been working with various agencies in putting migrating their current analog systems onto digital transports to repeater sites and positioning those systems to work with IP based two-way radios and ancillary devices required for a modern Land Mobile Radio (LMR) system.

If anything, the real learning starts before and after the licensing process when one looks into the various skills and techniques that go into the hobby. Much of what i learned is by picking up a book discussing topics directly and somewhat or remotely related to radio; both amateur and commercial as I have my General Radio Operator's LIcense (GROL) with microwave endorsement. I, too, received my final licenses well into the appliance era.

I started by learning software (actually assembly language at the time) by writing machine code into a debugger. Then learned how to use a compiler for the Higher Order Languages. I learned my radio by putting together kits and hacking mods onto it. Some successful and others that let the Smoke Genie out of the bottle! I got my training in digital logic similarly. (My take on "dead bug" assembly technique is having an IC with it's innards exploding in a flash and puff of smoke.) I have also learned how to repair cars, do rough carpentry, electrical, and routers and analog and digital communications systems in the same manner. Masters of any of these? Definitely not. But i have an under standing of how things work so i can figure out what to do next if things don't seem right. I can perform the physical installation of microwave systems and routers and get circuits connecting but let the masters of each technology do their thing, then I make the whole thing work together.

If I had the time, I would love to deeply dive into a subject to come up with the mastery. But because I am still gainfully employed and need to remain somewhat of a generalist, that will not happen in the near future. That being said, I still enjoy dinking around proven circuits to see how changing things affect performance. Radio is particularly good with this methodology as the same radio will not perform universally well for everyone as there are a multitude of variables which affect performance that are not spec'd on a data sheet. Start with a formula (schematic); build it as specified; then proceed to get your hands dirty! Transmitters are probably the easiest as they can be put together with one or two transistors - the late Dave Ingram was probably the biggest evangelist here. Gratification is somewhat instantaneous as you can hear the output in a receiver. Receivers require a bit more but basic crystal/diode or regenerative receivers as extremely flexible and forgiving of playing "what if" with - so what if the coil you wound has a an extra or missing turn. (I just saw a short article on using an antenna tuner as a front end for a crystal receiver - something i have wanted to try but will probably do so now that i have seen it in print. It's really a terrible idea as receivers thrive on resonant front ends for best signal selection while transmitters typically require a reactive match to the antenna for maximum

power transfer which an antenna tuner tends to support; however, I have the parts for it and it's very simple to put together!).

Anyways, don't be disappointed in the current licensing process. It's just a product of the times. Instead, (I typically) find a good bookstore (the good ones are going away quickly) that has books on basic tube and transistor theory. I like books as they are easier to read and annotate. I have not been able to do so with as much success with web based research. Develop a good junk box with new and used parts that can be used to experiment with. Start with a basic VOM (I like analog meters best as I can read a meter sweep faster than waiting for an ADC to settle down on a value and report it to a digital display) and see what happens when biases and inputs are changed on tube or transistor circuits. Change the loads on the outputs to see what happens. Build a kit and change the circuit to see what happens. Above all, don't be afraid to break things because it will naturally happen when you experiment. The great inventors never got it right the first time. If you have read through the previous posts in the group, it is a miracle that we are all still alive and can tell about it. It's all part of the learning experience! (or I was an 800VDC dummy load).

Ok , I didn't realize that. So might I suggest learn to memorize your favourite Vacuum tube osc circuit. Mine happens to be the hartley but the colpits is similar only using centre tapped Cap pack rather then a coil. Regens are basically nothing more then underpowered oscillators with a set of phones and method of controlling rate of feedback. Otherwise the circuit is identical. It would take most of us about an hour to learn to draw from memory a osc circuit diagram. By noon everyone could have one in their head. Then the job becomes so much simpler.Otherwise one winds up following circuit diagrams and someone elses design forever not quite understanding what is going on and not knowing what is important and what isn't important. What isnt important in relationship to what is important is the key. and that comes with experience. Leonard just mentioned he guessed at the values for his Mk19 set. That doesn't mean they are hap hazard as some would be inclined to think. It mean he understands what he is doing and can and does get it up and running without a million questions and reams of somewhat pointless caculations. I would suggest the assignment to memory of a basic osc diagram , either vacuum tube if that is your flavour or solid state if you are inclined there would be the best thing you ever did for your hobby and it doesn't take that long. Next to that would be simple amplifier circuit. tube or SS . whatever your preference. The difference it makes in you building would be phenomenal. Instead of wondering in frustration as you build you would know. And like I said most of us can put a osc circuit to memory in a hour or so. certainly by noon today. Drawing it six times will usually do it with most of us. Keep a copy nearby if you wish but the difference it will make is huge.
For our test in the 1980s I had to draw a simple hartley osc , a simple colpits osc and draw a PA final with ampltude modulation applied. I remember I wasn't prepared for the last one and so took an guess. Turned out I drew a method Motorla had explored and the inspector in a previous life had been a Motorla engineer so I got lucky.
I will be honest here and tell you it took me a while to realize how significant knowing these circuits was. One day I put two and two together which I should have done many years ago. It was a lightbulb moment for me and i am somewhat ashamed it took so long to make the connection. Hopefully this will encourage at least a few to give it a try. It will change everytthing. You'll see. An hour of pain for a lifetime of gain.
Worst case scenario? What could it hurt?

Yes Don.... I agree with your learn it... know it forever logic.
Thats why I came down the regenerative and tubes path.
The documentation is 100 years old and refined to the point where the
1920s magazines
explain to farmers how to build radios.
I like the idea that there is an attempt to make the builder understand
why the circuits work instead
of the way the solid state electronics cookbooks have 2,000 circuits
without any explanation of what
the circuits are doing.
Or worse.... expect the builder to have an electronics degree and KNOW
calculus.

And to Kevin
>
> The exam is not an end to learning.
>
I've been electrocuted.... when I was 12 years old.
Mains power... at a meter... was thrown 30 feet.

sort of kept me away from experimenting with tube power until finding
out that 45 volts on a TYPE 30 tube
meant five 9 volt batteries in series.

Interesting, Rob!

My first attempt didn't work either, so I put it aside until
I have time to tinker. Unwisely, I soldered everything :-)

Has anyone else tried and/or modded this VK3YE design?
On the mp3, what is the origin of the very loud buzz?
It sounds like a router or switch-mode device.

Michael

Topic: 25840 Message: 26606

Hi Rob

I belive, you catch that buzz, because your antenna doesn't have a dc path to ground. My reception is completely clear without any hum. If your antenna impedance is 50 Ohms, then try a 50 ... 100 Ohms resistor from your antenna connection to ground.

Regarding the reception quality i can't recognize a big difference between the ceramic resonator and an LC circuit.

Best regards,
Bernd

Topic: 25840 Message: 26609

If not from a naughtylocal digital source and not relieved
by antenna-pleasing, it might be a hum loop in the
board layout. Is it the same with mains or battery
power supply? I would try anew with a copper-clad
pcb, single earth point, short wiring etc.

Depending on the strength and proximity of nearby signals,
the resonator should offer better front-end selectivity
than a LC circuit, but not as narrow as a quarz.
Many moons ago I tried a quarz plus 40673 mosfet front-end
in a simple receiver for monitoring a SSB fixed-channel network.
It was a bit narrow for SSB, but certainly effective in
suppressing adjacent and tropical static interference.

But I had best keep quiet until I have found time
to retry my own failed attempt at reproducing the VK3YE :-)

I have experienced that same loud buzz humming in my simple crystal
radios also
so I'm not real surprised by it at all.
I was sort of hoping for better selectivity with this layout.

I definitely will be buttoning down the circuit on soldered PCB.
The wire wrap version was strictly an attempt to learn how to wire wrap
a fast prototype
AND
I considered it a success because noise hum or not..... it heard HF CW
that I could copy.
Given just that much success defined the next chase to RF front end
filters and audio passband filters.

IF the wire wrapped components.... all soldered to PCB ...yields the
same results
then
I will build more wire wrap circuits.
If soldered components go quiet then the wire wrap will be used for
non-RF circuits.

As far as your circuit not working goes.....
I found that the amount of regenerative resistance needed tweaking.
I had nothing ...total silence ... until I shorted out the 220K resistor
between the regen pot and the positive
volts rail cutting out that 220K.

So KEEP the ideas coming.
Nothing is ever a bad idea until somebody bleeds or gets pregnant.

Rob, do you get the buzz on other radios? Is it steady or intermittent? If you get it on transistor radios, then it must be something in the environment, like TV, or computers, or overhead power lines. My wife's radio goes berserk when ever I turn on my computer. We also get radar interference from the ships in Pearl Harbor sometimes. Right now I'm getting what sounds like steady ignition noise, but I think it's from my neighbors motion sensor lights. Some solar equipment will also cause interference. We live in a noisy, noisy world.

Leonard

I tend to believe its normal AC hum from household wiring because I only hear it on
a basic raw home brewed crystal radio and now this 716 receiver.

I do not have static on TVs or hear it on an MFJ9040 or other store bought ham radios.

Which leads me to believe its a construction and design issue of my experimental radios
that I left out of this basic experiment.

Rob, another posibility is your ground. A friend of mine was getting some interference (I think it was 60Hz hum) on his radio. He was connedted to a water pipe for his ground. It turned out that the pipe he was connected to was galvanized iron, but the house wiring was connected to the incoming copper water pipe. The pipes were connected, but there was several volts between them because of dissimilar metal action. Runnung a ground wire back to the electric panel ground solved the problem. Of course he could have used the AC outlet ground since it's grounded at the electric panel. I had a similar problem with my R-649A AC/DC radio. I solved it by putting it on an isolation transformer.

Good point, Leonard.

Dissimilar metals can form a primitive diode, allowing
"dirty" modulation to feed into a receiver. This can happen,
for example, at TV antenna connections between aluminium elements
and brass connectors and copper coax.

We look forward to a happy outcome of your sleuthing, Rob!

ahhhhh.... I wish I had something more complicated that debugging would
cure this hum BUT
my ground wire exits the radio room through a hole in the wall and goes
directly to a spike in the ground.
I could revisit the spike and connection... scrape something shiny again.

Thanks for the ideas.

Congratulations. I had to smile at your comment. "I am stunned it worked." The new transceiver I just did was also I am surprised it worked deal. The regen is so simple most wouldn't build it but even before I hooked up the audio stage I could tell it was a keeper. When I hooked up the audio I had some hum issues which by the way were not there before. Since it is Ac powered I worked away at it. Reducing the plate voltage to the audio tube helped a lot bring it from terrible to useable so I went at the PSU, a 12volt/120 output deal feeding a doubler. (need that for the transmitter section) . I recently bought a bag of 40 100 uf /450n volt electrolytics from China and so took a old audio transformer using the primary as a choke and added it after the doublers output . Now I have no hum at all. Never had such good luck before. I have spent several hours enjoying the regen section of the transceiver. It works very well. Been calling Cq with the Tx but so far no cigar (7040khz) however I have also tried with my 45 watt Cw rig with the same result so I am ok for now. I know this rig is putting out a decent signal compared to others I use regularly. I guess your ceramic resonator would lend itself easily to a Transceiver deal. n
Anyway,nice to see you stepping out there and giving it a go. Impressive! Hope you enjoy it for a long time.

Rob, I have a 10 foot copper pipe down in the earth for my ground. I measure 4 vac between it and the electric system ground.. I have a switch on my antenna panel that can select line ground, earth ground, or floating ground.. It comes in handy sometimes.

26618. VK3YE's Ceramic Resonator Regen NO BUZZ all fixed

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-12 05:47:51 UTC
From: Rob
Topic: 25840 Message: 26618

All fixed
new pictures and audio recording here:
http://www.learnmorsecode.com/716/716.html

I needed to experiment with the regeneration potentiometer values since
I didn't have a 50K pot.
First try at splitting the 50K in two using two 20K pots and soldering
the tuning cap to the board
AND THE BUZZ WAS GONE!!!!!!!!!!!!!!!!!

Just WOW.
Real big WOW.

This has been 18 months of research and examining how to build a short
wave receiver
REAL CHEAP
for the kids gigs and scouts
that WOULD receive Morse code.

18 months of examining how radio circuits work
and even how the parts were made... thanks to 1920s magazine PDFs.

But this is the first working radio I built during all that research time.
And I am just stunned at how pleasant the audio is.

Next task is an audio amplifier.
I have all sorts of options there ready to knit together.

Considering all my components came from China EBAY sales....
I think the cost so far to repeat this circuit is $7.

Congratlations, Rob!

We learn more each day, from our own and from each other's
endeavours. Fiddling with radios must be one of the best
senility delay therapies!

It will be interesting to hear how you tame the audio
and keep that hum at bay.

Senility Delay Therapy

hmmm.... an SDT....
My wife is going to be pissed when I tell her I got an SDT.

I've got ICs like LM386 and TDA7052 and discrete components like TIP31
and TIP32 and TL431
so I'm pretty sure I'm going to make some noise:

My experimental "goto" amplifier is a 9 volt guitar amplifier.
I found out that it uses a TDA7052 chip so I got some of them to play
music or radio:

Rob, if you use an IC like the LM386, be sure to use an emitter (source, cathode) follower between it and the tube circuit to match the impedance as Dave Newkirk suggested. Take a look at my Mk.21 in the Files section. The component values I used may not be optimum but it works surprisingly well.

Senility Delay Therapy

hmmm.... an SDT....
My wife is going to be pissed when I tell her I got an SDT.

I've got ICs like LM386 and TDA7052 and discrete components like TIP31 and TIP32 and TL431 so I'm pretty sure I'm going to make some noise:

My experimental "goto" amplifier is a 9 volt guitar amplifier.
I found out that it uses a TDA7052 chip so I got some of them to play music or radio:

Huh?
I am very familiar with your Mk21 circuit. I followed your mod 3C and 3D discussions
and stowed the images here so Arnie could see them too:
http://www.learnmorsecode.com/regenx/LM/index.html

and then
I bought some EBAY 6AK5 tubes and bases.
I did not build anything yet. I'm saving my tube rig builds for later.
I am gathering parts and learning why they work first.

BUT

my VK3YE ceramic resonator regen
IS NOT A TUBE radio

so how does what you are suggesting
"to use an emitter (source, cathode) follower between it and the tube circuit "
apply to this ceramic resonator circuit?

http://www.learnmorsecode.com/716/VK3YEmodKB3BYT.jpg

http://www.learnmorsecode.com/716/716.html

I took this radio out for a road trip tonight to dinner at my in-laws mountain top
house.... at 1600 feet.... sort of top of the world here.

I wanted to see what would happen if I used simple wire for an antenna instead of
my ham radio RYBOKOV antenna.

I tossed a spool of 22 AWG magnet wire over a 20 foot high tree limb
and used a screw driver as a ground rod.

I heard all sorts of CW and also found some Spanish broadcast radio.
I have to wonder if Arnie was on the air tonight.

I am really liking this radio.

Rob, the Mod 3d was the final version. Note that the output of the 6AK5 does not feed directly into the LM386. Because the impedance at the output of the 6AK5 is a lot higher than the input of the LM386, it tends to load the detector, reducing sensitivity. Putting a source follower (in this case) between them adapts the high impedance circuit to the low impedance circuit. It could have been an emitter follower or a cathode follower, all of which have high input and low output impedances.The improvement in the 3d over the 3c was clearly noticeable, thanks to Dave Newkirk.

In my head it is all coming together now...
- board layout
- earthing
- regen control
- 3819+386 AF

Methinks regeneration control voltage could be achieved with
a single voltage-divider pot and one resistor to the base.

Worth tinkering :
- two pots in series - one high R and one low R for fine regen control -
then, once optimised, replace the former with two fixed Rs;
- values of R to base;
- Cs around the resonator to optimise frequency range.

Good to know you are still around, Jara!

Beautifully presented designs. You would not want to
see mine...

The synchrodyne design would certainly be of interest
to many of us, BUT we would need more text, descriptions,
analysis, comparison.

Basic English would be fine for most of us.
In technical contexts, online translations are often
more confusing than helpful...

In pre-shaving years I was gifted a few pre-production OC70s.
I would not have risked one of them without multiple wiring,
battery polarity and data checks...

From a SK I now I have clusters of three and four legged things
with manufacturer markings unknown to googlenet and friends.

After meter checks and headscratching, I just try one.
Most survive, many perform even.

Almost any jfet will behave in a jfet circuit, more or less,
including those listed below.

If you have enough for sacrificial research,
the benefit will be SDT at the very least

I am told there be data sheets out there, trapped in a web.
You don't have to buy 10000 from the Middle Kingdom
to get the data.

:-)

The MPF102 will work for most applications.

2N5484 through 2N5486 are used to replace the MPF102 depending on application.

application.
73,
Jim Scott
++

And head scratching....
I am all for recycling.... but .... now that I can buy 1,000 transistors
for $10
I have completely given up on ANY loose parts that are not labeled.
I relegate them to snipping off the stiff leads and using the leads as
wire wrap posts.

This particular circuit cost less than the KNIGHTSMITE I built 20 years ago
and performed 1,000 times better so I'll be playing with this circuit a lot.

Rob, I'm not sure. Those FET's are pretty high gain and may not be suitable for follower service. But you never know until you try them. Personally, I would opt for a more general purpose FET. I know cathode followers have transconductance requirements but I'm not sure about semiconductors.

26637. "DC SW-3 Modified for Long Wave Receiver"

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-14 04:24:56 UTC
From: Hubert Miller
Topic: 26637 Message: 26637

When i mentioned that I had a schematic captioned "DC SW-3 Modified for Long Wave Receiver", a couple

people asked for the circuit. I do not have a scan available, but description follows. This paper came from

an estate of a man, Royal "Bill" Zinn, who had been a radio operator in the mid 1930s for Alaska Steamship

Company, and later ran an electronics surplus store in West Seattle in the 1950s. I also have some repair

logs documenting ship installations which mention the SW-3, so there's no maybe about it. I believe at

the outset of WW2, Alaska Steam replaced its elderly IP-501 receivers with the SW-3. Alaska Steam had

something like 5 ships running from Seattle up to Alaskan ports. I am guessing by the choice of tubes in

this set, the 78s, that it dates from around 1934-1935.

The "modified DC SW-3" uses tubes 78, 78, 76. There is no attenuator pot in the antenna circuit; RF gain

is by a 300R + 50kR pot in the 78 RF cathode. The detector coil has the feedback winding coming from the

78 cathode to ground. The 78 regeneration control is a 50k pot between ground and the +67.5 battery tap.

The RF 78 screen comes from a +22.5 volt tap on the battery. I don't see this battery voltage tap on the

other published SW-3 schematics. I'm pretty sure the A.S.S.Co. SW-3s were only equipped with coils to

cover the 500 kHz frequency. The HF receiver on these ships seems to have been the Sargent 10, also a

regen. One doc lists an passenger lounge radio, a home-entertainment superhet type; it might seem a

little odd to provide a more modern receiver for this nonessential use.

26638. RE: "DC SW-3 Modified for Long Wave Receiver"

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-14 04:36:17 UTC
From: Hubert Miller
Topic: 26637 Message: 26638

I forgot to mention this also: I do NOT know why these changes were made. It would seem

that the SW-3 was okay as-is, but Alaska Steam for some reason decided to modify several

of them.

I have never seen one of this particular modification. I bought a bunch of paper and hardware

from his widow, but then i moved to Omaha for a spell. Years later, at a radio swapmeet,

another fellow told me at the final-final estate sale, after Mrs. Zinn passed away, "They

found a number of SW-3's in cardboard boxes in the loft above the garage".

Hi all, here is my last synchrodyne for MW band. You need cca 5meter wire as antenna for near stations. Audioamplifier with 2xE88CC is my modification from russian schematics.

Best regards, Jara "Rat"

26640. Regen-synchrodyne for MW

Yahoo group: regenrx (2016 — 2017)

Topic: 26640 Message: 26640
Attachments: 4 described; binary payloads are missing from this source WARC

Hi all, here is interesting construction from Russia. Work as regen or as synchrodyne by setting. Very good construction! (But you must try coils).
It work better than ECH/PCH synchrodynes. No untuned preamplifier here.
And you can set it as "only regen" or as "synchrodyne too!!"
However, you must have a coil for feedback and for antenna.

I hope you find it helpful

Best regards, Jara "Rat"!

26642. Re: [regenrx] 1.5mH scramble or not scramble ... SINGLE ENDED AUDIO transformer

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-14 21:33:16 UTC
From: Daniel Donnelly
Topic: 26507 Message: 26642

Inregards to the home brew choke question.
I was a QC engineer for a transformer and capacitor manufacturing co in mexico. The thing about mexico is the attitude of engineers, practicality is the only important factor.Calculations would be made and then the choke or transformer would be built and tested ... with in the end, no matter what the calculations said, the # of turns would be varied to get the result needed. The result was excellent components sometimes made almost by hand.
I say that because while production runs were on standard wire lathes, if a prototype was needed (and the winding machines were all in use) I have seen prototype chokes and transformers made in one evening using nothing more than a slow speed drill held in a vice and an armature supported on a wooden block.
The point is that fancy equipment is not needed to produce an excellent one of a kind product.
What is needed is good components, patience and (especially) care in winding the layers of wire.
And no for power line frequencies the choke CANNOT be scramble wound.
Dan

26643. Re: [regenrx] 1.5mH scramble or not scramble ... SINGLE ENDED AUDIO transformer

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-14 21:55:00 UTC
From: Rob
Topic: 26507 Message: 26643

So considering the hands on approach..... simple hand tools.....
I was wondering if a single layer of wires.... not scrambled.... should
be wound and then should that layer be covered with
tape... and the next layer wound , then tape again.......
to get an extremely uniform choke.
I say tape...just because my antique choke looks like all layers are
separated by tape.
BUT
I was wondering if the layers could be separated by KAPTON tape.

http://www.learnmorsecode.com/regenx/choke/chokes2.jpg
Another interesting note... the huge size of the antique compared to the
brand new choke.

Next one I wind will be with 32AWG instead of the thick 22AWG wire.
the antique choke arrived in the mail and I peeled it apart to examine
what gauge wire was in
and compared it to 26 gauge wire and then
concluded it was definitely made with something much thinner.
http://www.learnmorsecode.com/regenx/choke/index.html

I sort of shelved the tube rig choke research while I waited for 0C3
tubes to arrive in the mail
and to do some metal work... rebuild an attic air conditioner:
http://www.learnmorsecode.com/air/index.html

26646. TRF to REGEN

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-15 14:45:43 UTC
From: Tim Haake
Topic: 26646 Message: 26646

I have collected over the years a few TRF receivers. Several are real beauties and a few need the whole gammit of wood restoration. In all they may have been a marvel of the day but a pain to use on any regular basis, at least for me.
SO, I am thinking about taking probably one of my "3-dials" since that's mostly what I have, and not a pretty one, and making it a regen to see what I come up with on the BC bands.
Has anyone put any effort serious or otherwise with making a conversion like this? I've got several Ideas on doing it but want hopefully some comments if anyone wants. After all the big intent of those designs was NOT to make the amplifiers interact with each other.
 Close to a regen but no cigar. Wonder what the thinking was?
TIM

Dear Tim

What a shame, don't destroy a working receiver. There are a few other possibilities. Either you exchange one receiver with somebody else. You could build a regen receiver by yourself, using more modern tubes.
Or you could buy one from ebay, this is an example only, have a look:
Very Rare, Vintage National SW-3 Regenerative Receiver - 1930s http://www.ebay.com/itm/Very-Rare-Vintage-National-SW-3-Regenerative-Receiver-1930s/182168693745

A few issues with this ad. SW-3's are not "very rare." That's eBay hype. Also, the seller should have specified which coil set is in the set. Also, I wonder what kind of shape the under-chassis area is in, and if the bottom cover is included. They are missing sometimes.

You I'm only putting in my two cents because I have some experience with SW-'s. Great little sets. Not abundant like S-38's or S-40's, but not "very rare." But they are getting hard to find in nice condition.

Everything sold on Ebay is “Very Rare”, if it’s no longer being manufactured.

The photos on that listing are pretty crappy. Hard to tell what’s discoloration, camera effects, or rust.

Would have been easy enough for the seller to pull the tubes and coils and look for identifiers. But

that’s beyond many people’s ability.

You can easily convert a TRF receiver to a regenerative one by connecting a Q-Multiplier onto the final tank circuit of the TRF. A very simple, but a versatile Q-Multiplier can be made with a differential pair, see schematic below.

Just curious, looking at the Q-multiplier circuit, and being somewhat familiar with TRF receivers, how does one tie the Q-multiplier shown in the schematic to the final tank circuit. I assume the circuit shown connects to the detector's tuned circuit some how.

26656. 716 regen and wire wrap

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-18 03:18:04 UTC
From: Rob
Topic: 26452 Message: 26656

I got a dirt cheap rechargeable electric screwdriver.
The smallest one made.
Put masking tape around the ink cartridge to make it fat enough to
center it snug in the bit holder then some masking tape holding it
secure and tape on the direction selector to never trip it out of
forward direction.

This wire is 22AWG magnet wire.
picture :
http://www.learnmorsecode.com/716/wirewrapelectricscrewdriver.jpg
http://www.learnmorsecode.com/716/716.html

Kids could do this.
I don't mean make the tool....
I mean WE make the tools and then do point to point wiring builds with
the kids
using these tools..... and take home a radio... without soldering.
I liked the 22AWG magnet wire.
Its thick enough to not be as fragile as the 30AWG wirewrap wire while
still being thin enough
to spin down and coil on a pin.... or component lead.

I brought this 40 meter regen to my local ham club meeting last night
and hooked up an antenna and
ground for show and tell.
AND
brought the wire wrap tools and a few guys played with the tools.
One of the hams did show us proper methods because he built IBM 360
mainframe
computers with wire wrap for 20 years. I thought that was cool.

It seems the square pins are the "gotcha" with this technology.
The pins cost 10 cents each. No way around it.
So if you build a board with 100 pins it WILL cost $10.
Does anyone know of a similar type of pin for wirewrapping that pushes
into a board
and costs pennies, not dimes ?

26658. 716 regen and wire wrap 2X20K pots with NO 220K resistor

Date: 2016-06-18 15:55:34 UTC
From: Rob
Topic: 26452 Message: 26658

Can any of our "non-beginners" here give me any instructions about this concern?
I am not an electrical engineer. I am a amateur radio hobby electronics dabbler.

The circuit works great with the two pots set at halfway points .... around ...10K.
What measurement should I do to figure out if there is too much current or voltage on what parts?

AND
If I were to replace ONE pot with a fixed 10K resistor....
which pot would that be? The one attached to the power rail or the one attached to the ground rail?

I definitely agree that turning the two 20K pots to zero will short the 9volt battery to ground.
BUT
the purpose of those two pots was to find a regenerative value resistance that worked without
the 50K ohm pot... just because I didn't have a 50K pot.
My first pass at this circuit had one 220K resistor in series with one 27K ohm resistor and then one 20K
pot.
It was my way of getting away with not have a 50K pot.
BUT
I got no regeneration at all until I removed the 220K resistance from the regeneration circuit.
As soon as I removed that 220K resistor ...it came to life.
So then I figured that TWO 20K pots could be used to better tweak what value actually worked.
Which gelled into retiring the 220K and 27K resistors.
http://www.learnmorsecode.com/716/VK3YEmodKB3BYT.jpg

I am not alone in this 220K resistor being dropped out of the circuit to make it work.

You could get some old Timey Square copper bus wire, cut a half inch or so, mount, and wire wrap. Antique radio supply (www.tubesandmore) has it. Used in the twenties radio sets. It is about 1/16 inch square cross section. Other gauges might be available.

I don't see the need for two 20K pots, even if it's a dual pot. Just ground the bottom of the upper pot and get rid of the lower pot.

When making a modification involving two pots in series I usually put a 5 k 1/4 w resistor on the ground side.just to make sure that I don't accidentally short out the power supply.
one other thing that you might try is to replace the 20 k pot on the ground side with a 5 k pot and use that pot as a vernier contrlol.
I have done that several times on "genny's" that wsnted to "snap" into oscillation. It seems to work very well and makes it easy to control the regenerative action.

26664. wire wrap square wire sources

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-18 20:03:10 UTC
From: Rob
Topic: 26452 Message: 26664

Thanks for the square wire lead Ken.
I did buy some
and
then poked around the net and found other square wires...used for crafts....
18,20, and 22 AWG... ordered some ....
we'll see whats good for circuits.

I have bought plain craft wire from Walmart.
Some have an enamel color coating.... some are bare wire.
I would like to get away from scraping a color coating for pins ... but
is seems to me that
scraping a color coating off a square wire could be a lot easier than
scraping a round wire.

This is all an experiment in craft materials for me to find out if we
can make something
with the kids.

Q4 in the MC1648 IC is an emitter follower stage for the ALC amp. Q5. Emitter followers often form parasitic Colpitts oscillations due to unwanted capacitive voltage dividers involved. Which measures are taken to avoid unwanted oscillations of stage Q4? The same goes for emitter follower stage T3 in the lowermost schematic below.

Schematic of the MC1648 VFO IC

From: parkerp@...
Topic: 26666 Message: 26666

Built many regens but no Q-multipliers before.

My starting point was the first circuit at A crystal receiver with a Q-Multiplier. - TheRadioBoard Forums http://theradioboard.com/rb/viewtopic.php?t=6660

A crystal receiver with a Q-Multiplier. - TheRadioBoard Forums http://theradioboard.com/rb/viewtopic.php?t=6660 Re: A crystal receiver with a Q-Multiplier. Postby Pat Pending » Sat Dec 05, 2015 12:34 am I've added this regenerative "Q" muliplier to a "crystal" set.

View on theradioboard.com http://theradioboard.com/rb/viewtopic.php?t=6660
Preview by Yahoo

It worked first time but improvements were possible.

Here's what I did:

1. Tapped the BC548 emitter well down the coil (about 4 turns up from earth).
2. Reduced the 100pF coupling capacitor down to about 3.3 or 4.7 pF.
3. Connected the free end of the 3.3 or 4.7 pF to the top of the coil/variable capacitor junction

I have found the Q multiplier doesn't improve the volume of stronger stations. Neither does it greatly help cut out overload from strong stations. But it does improve selectivity somewhat and makes weak stations audible that previously were not. At night there are many weak carriers. My listening has been with 2000 ohm mangnetic headphones and it is possible that some of the weak carriers will be identifiable if an audio amp is added.

26667. Re: Adding a simple Q-multiplier to a crystal set

Topic: 26666 Message: 26667

Quick update: An even lower capacitance was even better. The 4.7pF was replaced with about 50mm enamelled copper wire wound over the connection to the variable capacitor. This cuts the number of added parts to just 4 (BC548, 10k, 100k, 100n).

26668. wire wrap square wire home brew pins work

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-22 17:57:24 UTC
From: Rob
Topic: 26452 Message: 26668

Wire arrived today.
The antique bus wire is huge. Not a feasible replacement for
wire wrap pins but I can definitely see using the bus wire for
larger pin tasks. The tool would have to be modified with a much bigger
bit.

BUT

21 gauge wire worked with the home brew electric tool.
21 gauge wire definitely is a tiny bit too big for the standard wire
wrap tool
but the mission was not to use the expensive tools.

BEADSMITH CRAFTWIRE
21 Gauge NON-TARNISH
SQUARE ROSE GOLD

Noting that the color ROSE-GOLD is what makes it NON-TARNISH
and it scrapes off just like any enamel coated magnet wire
so if you really must wire wrap a project but you can not find
real wire wrap tools and wire and pins then this stuff really
could work for you.

http://www.learnmorsecode.com/716/21gaugeSQUAREroseGOLD.jpg
http://www.learnmorsecode.com/716/716.html

I'm thinking this wire could be pushed into a soft pine board
or drill pilot hold and glue them into the holes.
21 AWG is not a tight fit in VERO board.

I have 18 AWG square wire coming. We'll see what happens with the fatter
wire.

Either size..... this would definitely be just fine for kid projects
using complicated
circuits and print a baseboard guide circuit that gets glued to the
board before the pins
are set and then also use color wires.

Has anyone experimented with proximity fuze tubes? I used a couple in my Mk.19. They worked very well at first, but now aren't doing so well. The tubes were not designed to last very long, maybe 10 seconds or so. I breadboarded a few to see if I could develop some characteristic curves, and noticed that they degraded the longer I kept them on. Therefore, I don't think it's worth persuing the project any further. Now I'm working on some submini tubes that seem to be hearing aid tubes. They're triodes and the only markings on them are 433 and 447. They seem to have a greater mu than the proximity pentodes and have a higher frequency response, up to 10MHz or better. The proximity pentodes seemed to peak around 600KHz, maybe because of the breadboard setup. With a crystal the 433 and 447 readily go into oscillation, so I'm sure they'll work as regen detectors. The next step is to see if I can measure the mu and gm.

Leonard - your observations are very interesting. I thought the minimum non-gas tubes were rated at was 100 hours, such as the 5676 tube. I first learned about
the limited life hours rating recently in a military manual that described the tube purpose rather than detailed specs. I had known for some time that some gas
tubes, and i'm thinking of the RK-61 submini, had lifespan rated in hours. (This was a gas tube used in radio control ship and plane models of the 1950s, used in
a superregen circuit, usually on 27 MHz CB.) The texts on that tube say the larger the plate current, the shorter the life of the tube.
I wonder what exactly is going on with your V.T. fuze tubes.
I think they operated on around 300 MHz in the V.T. fuze weapon. I have a book on the V.T. fuze "The Deadly Magic", but it's packed away now.

Hue, I have a copy of OP1480 on VT Fuzes but I can't find any data on life expectancy of the tubes or battery (energizer) voltages. My opinion is that the emission of the filament depletes rather quickly, since the tube is intended to last only for the time of flight of the prokectile. I used to work in Naval Ordnance and never thought to look up any data on the VT fuzes at the time.

Rob, A Google for square copper wire produced so hits in gauges from 10 to 24. For example....
https://www.google.com/aclk?sa=L&ai=Cn99syWhsV9WNBIGm-gPNjrCgDon1u7AH2bbRvMcBybHunrYFCAkQDSDDkeQeKBRgyZ79jOSksBTIAQeqBCpP0H8kbvVjuRkKI5QPS3AwZ1qGvKopJT_8dTKOBogCMMxNH7u9j_b0ITbABQWgBibYBgSAB9uAjhWQBwOoB6a-G9gHAeASiKzilaT_-afsAQ&sig=AOD64_3HVKWZ7r8qkNhkjacQhs_ON_f3ig&adurl=http://rover.ebay.com/rover/1/711-117182-37290-0/2%3Fmtid%3D1588%26kwid%3D1%26crlp%3D53601919689_324272%26itemid%3D281608645956%26targetid%3D186358929609%26rpc%3D0.24%26rpc_upld_id%3D72320%26device%3Dt%26mpre%3Dhttp%253A%252F%252Fwww.ebay.com%252Fulk%252Fitm%252Flike%252F281608645956%253Flpid%253D82%2526chn%253Dps%26adtype%3Dpla%26googleloc%3D9028554%26poi%3D%26campaignid%3D239125209%26adgroupid%3D14978428809%26rlsatarget%3Dpla-186358929609&ctype=5&clui=35&q=&ved=0ahUKEwignJWPn7_NAhXCdSYKHbJTAuYQpysIaw&ei=yWhsV-CTAcLrmQGyp4mwDg

Brass square is out there too.

26674. wire wrap square 18 gauge square craft wire fits vero board

Yahoo group: regenrx (2016 — 2017)

From: Rob
Topic: 26452 Message: 26674

www.beadalon.com brand
GERMAN STYLE WIRE
18 GAUGE SQUARE
SILVER PLATED

comes in 1.25 meter length for $7.50 which makes 125? pins .....
perhaps costing 6 cents per pin.

It has no coating and is conductive so no scraping any color coatings.

It fits very snugly pressing into the holes in VERO board.

If I had to make pins.... this is the stuff I would use.

I also got some 20 gauge. The 20 gauge is thinner and slips freely
through VERO board holes.

Both 18 and 20 are too fat for standard tools but wrap nicely with the
ink cartridge tool.

I can also see using this wire as coil mounting pins.

WOW
COOL!
THANKS KEN!

Your EBAY link shows 18 gauge sold in quantity of 50 feet costs $27.18
which would make 1,524 ten millimeter pins.... at a cost of 1.7 cents each.

I do not get it. A Q multiplier works by regeneration, essentially an oscillator. That is the same as a regen by itself. So, why have a crystal set in front of it? Maybe just an extra tuned circuit? Regards – Mike

I have always wanted to build a WESKIT just to say I did it. I figured I would try to make a cabinet just to keep it somewhat authentic.

MY SCHEMATIC is very similar but is a phone modulated version. I never made it passed the "start" hurdle since there are no"Walkie-Talkie transformers to be found. I considered on trying to wind my own but that idea got pushed aside quickly. It is an interstage transformer 3:1 BUT with a carbon mike winding added to it. One or two transformer companies produced it. I have part numbers but you would need to find one in a very old junk box.

I am happy to hear that this was areal produced kit and not someone's idea just running amock.

Any comments would be greatly appreciated on the modulated version.

Who produced the ‘real kit’ ? I missed that email. WESKIT didn’t produce any modulated transmitter and as a very small operation, they never commissioned

any special part like a dual-winding audio transformer. Their kits didn’t use an audio transformer at all, because that would have escalated the price out of the

toy class.

It's an incremental improvement to a crystal radio, that can be turned off so you have the original crystal radio still functioning. As a teenager I remember buying surplus gear such as the ARC-5 series of radios, and once working one would proceed to add improvements on at a time to end up with a much better radio, I was a good way to learn how radio circuits work and how to make them better.

I agree that all experimentation can be a learning experience that I do not intend to impede. My comment was only that, hey, you have a crystal set as a receiver, and, you have a Q multiplier that is also a receiver. Only difference id that when used as a real Q multiplier it was tuned to the IF of the companion receiver. In this use, the tuning is done by the crystal set circuit and the feedback for regeneration is by the added circuitry. It is no longer a crystal set, but a regen anyway. Regards – Mike

But a q-multiplier is not a receiver, it doesn't not detect signals, it also has no tuning circuits of it's own, but uses the radios already existing tuning circuits It's a very special case of regeneration to add to existing radios but not radically change them. When I worked on the ARC-5 radios I added a Q Multiplier to improve the sensitivity and the selectivity, but it required no changes to the original circuit of the radio, it still used it's original detector. Subtle differences but enough that the q-multiplier and a regenerative detector are not the same thing.

Regenerative detectors are still used often as shown on this list, but q-multipliers are nor often used at all so for him it was something novel to try out. A Q-multiplier can also provide a notch in the frequency response to kill an undesired signal, something that a regenerative detector does not provide.

26685. OT: "The Hallicrafters Hour" radio show posted on my Box site.

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-25 04:28:43 UTC
From: Phil
Topic: 26685 Message: 26685

Hi All,

I just put a copy of the
"Halicrafters_Hour_450402_Guest_-_Hildegarde.mp3" up on my box site for
the enjoyment of anyone who may be interested.

This show from 1945 features the Hallicrafters line of radio equipment
(no surprise there) and appears to basically be an ad for their radios,
marketing to the expected post-war military crowd.

Some of you may recognize the callsign W9WZE, Halligan's own callsign
(the father of Hallicrafters).

Yes, I just noticed that Hallicrafters is misspelled in the file name,
but I didn't notice it until after I'd uploaded the file. I didn't name
the file, it's been in my OTR collection for years, I have over 100,000
old radio shows.

The link. Please download only if you're really interested as I'm
posting to several groups and expect the downloaded bandwidth will
exceed my monthly allowed "Box" bandwidth. Thank you.

26686. Which way does this capacitor go

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-25 08:55:22 UTC
From: Rob
Topic: 26666 Message: 26686

I'm building an audio amplifier for the 7.16 regen circuit.

I found a circuit on the web that uses an MPF102 pre-amp and a TDA7052 amplifier chip:

I put it here to share it:
http://www.learnmorsecode.com/amp/1w_Punch_amp_schematic_MPF102andTDA7052.jpg

The circuit says C1 is 1u
which I assume is 1uF
an does not show a + symbol or curve so I would think that capacitor is not a polarized electrolytic.
So what IS it?
I have no 1uF capacitors here that are not polarized electrolytic so I'm sort of stumped.
Can I use my electrolytic 1uF cap or must this C1 NOT be an electrolytic?

Which way is the correct way to point a 1uF electrolytic cap?
I found multiple amplifier schematics on the web that use this TDA7052 chip that show that capacitor as 1uF and 2.2uF and points with the + toward the TDA7052 input pin
and another schematic with the + pointing away from the input pin.

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } If you do not have the standard non electrolic cap, and it is 1u. You could use the gimmick capicitor. Two wires twisted together. It would reduce your parts count.
Keith.
I have not had coffee yet, please excuse any spelling faults.

I seriously doubt that you can get 1 microfarad of capacity from a gimmick capacitor. You might get a few picofarads.

It was asked if the cap is electrolytic. No, it is a monolithic or paper film and they do make monolithic and paper film caps up to a few microfarads. You can also take 2 electrolytic capacitors of 1mf value and wire them bucking (negative to negative or positive to positive) which makes a non polarized capacitor.

I agree. There is no way you'd get more than a few picofarads out of a gimmick capacitor.

In the circuit diagram, unlike C2 which is an electrolytic cap, C1 is drawn with two straight lines and no "positive" marking so that indicates a non-electrolytic capacitor. It won't be that difficult to find a 1uF film capacitor if you should wish to go that route.

Actually these days you can get non-polarized film capacitors in much higher values. I've seen them available up into the hundreds of microfarad range, but they tend to get very large in size and very expensive, especially for ones that have higher voltage ratings suitable for vacuum tube circuits.

THANK YOU for the suggestions.

I found a picture on an EBAY listing:
50pcs Monolithic Ceramic Chip Capacitor 1uF 105 50V Pitch 5.08MM New M

..... and for a dollar.

Is there any reason to NOT use these monolithic ceramic capacitors instead
of a pair of bucking electrolytics?

Is there any reason this circuit cares if I use just one electrolytic?

http://www.learnmorsecode.com/amp/1w_Punch_amp_schematic_MPF102andTDA7052.jpg

or if the direction of the electrolytic is one way or the other?

I'm just trying to wrap some brain cells around the idea that I did find
both directions in
the multiple circuit examples on the web using this TDA7052 amplifier chip.

What did WESKIT call this model?

The only kit of theirs (that i am familiar with, but possibly things continue to pop up) that does this is the “Midget Radio Company” (of same Kearney Nebraska)

“Tinidyne” radio-talkie, page 27 of July 1940 Popular Science. This thing wasn’t advertised very long. It says 100-150 foot range and size 3 x 4.75 x 1.5 inches.

I think two tubes; plural but number not specified. My thinking is that they used the headphones for a microphone (dynamic microphone) but the headphones

were not included in the price. If you have the construction docs for that radio gizmo, i think it’s wonderful they survived, and if you publish them, that would be

doing many Midget Radio Company – Western Radio Company – WESKIT fans a great favor. The price of the “Tinidyne” was $5.99
I still would be astounded if WESKIT or Midget Radio Company used a 3-winding mic transformer in any of their kits. That was an expense item i just don’t think fit

their style of ‘minimum parts count’ and ‘minimum expense’ product.

I have the WESKIT BN-1 and Sky Rambler receiver, a Pakette, some VHF converters, a WESKIT catalog and some of the instruction sheets which came with their

crystal radios. (Some of the crystal radio lit is pretty optimistic, like connecting the antenna clip to your bicycle. Yeah, right, if you’re next to the transmitter site!)

The 1950s toy “Walkie Talkies” Western Radio (same company) advertised were simply two handsets which used war-surplus sound-powered elements. The ads

didn’t exactly emphasize that the walkie talkies needed to be connected by wire.

regards-

Hue Miller

The “Tinidyne” ad says complete with flashlight batteries inside and “Mike-Phone” (quotes verbatim). “Mike-Phone” means they are using the headphone

as a dynamic microphone. (Some of the 10-in-1 kit type things did that too.) (It “sort of” works, in my experience). So if your kit instructions have a carbon

mic and mic transformer, then the instructions you have are not the “Tinidyne”, and i’m wondering what kit it was.

The only reason to use 2 bucking electrolytics is if you need a non polarized capacitor of that value and do not have it in any other form.

Personally I would use the ceramic or monolithic capacitors as the footprint is smaller and takes up less board space.

Good luck.

The mission is strictly to build an audio amp for the 7.16 ceramic
resonator regen circuit:
http://www.learnmorsecode.com/716/716.html
and
if at all possible to use the dirt cheapest ..and easiest
configuration..... so it can be successfully repeated with kids...
scouts.....
for the lowest cost because all the radios will be donated by
volunteers... geeks like us.
Its not a money making venture.
It looks like the total cost could be kept under $5.... not including
the 9 volt battery.
AND
it doesn't take a $5 DURACELL battery to run this thing.
I've been using dollar KODAK 9 volt batteries.

The TDA7052 costs 35 cents but uses less supporting components and
sounds better
than cheaper audio chips like LM386 so I was looking to learn more about
how to use the TDA7052
http://www.learnmorsecode.com/amp/1w_Punch_amp_schematic_MPF102andTDA7052.jpg

I'm trying to keep the parts count low so the kids have less chance of
construction failures.

And there will be no tube high voltages.

Higher value paper film have been around for decades. Tektronix used to use 5mf and 10mf paper film in their scopes. 1mf monolithic were also common. Now it is harder to get things in higher voltages though since most things have gone solid state. 12 volts being the most common but still see solid state devices to 48 volts as used in some high power amplifiers.

Using a monolithic would take up a lot less room on a board than using a paper film and they are cheaper too.

You have lots of options for that circuit you posted.

Good luck.

Speaking of batteries, i was at the Dollar Store yesterday picking up some things.
(I have found some great books among their “remaindered” book offerings, and if you choose very carefully, you can actually find

healthful food items.)

Anyway i needed some AAA batteries. They had two brands, “Sunbeam” 8 “Super Heavy Duty” for $1. (i have found these aren’t quite

what i would call “super heavy duty.”)

The other brand was Panasonic, which was my choice, as i like my Walkman-type radio to not suddenly die when i’m out hiking.

In the Panasonic packaging, there were two offerings.

One package had 2 batteries for $1.

The other package, exactly the same battery, had 3 batteries for $1.

It was a tough decision! I was trying to understand the rationale. Maybe this was some kind of New Age consciousness at work:

Maybe you only needed 2. So why take more than you really need? Resist greed!

(I couldn’t.)

What i SAID was

1- WESKIT did not produce a modulated transmitter or transceiver, except for a Western Radio branded 1-transistor “broadcaster” handie-talkie.

(BTW, Western Radio apparently got in trouble with the law, over their distance claims in early ads for this kit, according to an article

in Electronics Illustrated.)

2- WESKIT did not use an audio transformer in any of their products, let alone a 3-winding mic transformer.

I did NOT say such a transformer does not exist, as i have such transformers.

What you are building, it sounds like, is a replica of the BN-1, with modifications.

Subject: [regenrx] Re: Transceiver build with regen completed

Well I am not going to get into a pissing contest over the Weskit but I DO HAVE THE BUILDING DOCUMENTATION complete with box and construction notes and if you would like I will produce the part numbers for the "walkie talkie" transformer if you like that you say never existed. I have PN's from two different manufacturers. I suppose there is a ghost left from the old WESKIT days lurking on the internet making up all this phony docs and manufacturer specs that I have in my hands??

Rob,

Just go ahead and use the 1uF electrolytic, if that's what you have. Connect the positive (+) end to the drain of the MPF102, and the negative (-) end to the TDA7052. This should work fine business. BTW, it doesn't even have to be a 1uF capacitor. I would venture that if it's value is much higher (like 10 - 20uF) your circuit would work for the purpose intended.

26700. Submini Tubes

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-25 21:34:30 UTC
From: Leonard Meek
Topic: 26700 Message: 26700

I just ran some tests on my submini tubes, 433 and 447. The results for the 433 were as follows:
Gm=290
Rp=138K
mu=40

The results for the 447 were simular;
Gm=200
Rp=140K
mu=28

Both tests were run with the positive filament voltage on pin 2, negative on pin 3. When I reversed the voltage on pins 2 and 3, I got the following results for the 433:
Gm-200
Rp=150K
mu=30

I realize that the polarity of the filament connections can affect the bias felt on the grid in some tubes. In any case, the accuracy of my tests are sketchy at best, being done on a cluttered bench amid piles of junk. Also, my calculations may not be entirely believeable. But the relative figures will help in predicting the results of my next circuit creation.

Leonard, how did you determine the filament voltage for those tubes?
I am still perplexed by your report of how quickly these tubes seem to degrade.
I don't see how the designers could lab-test the superregenerative proximity fuze design and optimize it, if that was the case.
I think the Gm figures you got are not out of line with subminis of that era. The Rp seems a little bit low but i only say "seems to me (only)".
Interesting info on the tubes anyway. Are they marked as to manufacturer, or any kind of date-code?

Subject: [regenrx] TRF to REGEN

I have collected over the years a few TRF receivers. Several are real beauties and a few need the whole gammit of wood restoration. In all they may have been a marvel of the day but a pain to use on any regular basis, at least for me.
SO, I am thinking about taking probably one of my "3-dials" since that's mostly what I have, and not a pretty one, and making it a regen to see what I come up with on the BC bands.
Has anyone put any effort serious or otherwise with making a conversion like this? I've got several Ideas on doing it but want hopefully some comments if anyone wants. After all the big intent of those designs was NOT to make the amplifiers interact with each other.
 Close to a regen but no cigar. Wonder what the thinking was?

I think WESKIT and the Mitey Mite were two different things. If you mean the radio that used something like 12AU6 50C5 35W4, that was built elsewhere.

I couldn’t immediately find it by google, but i know i read an article on the web about it.

The main problem i noticed about the Mitey Mite is that the antenna went right to the top of the trans tuned circuit – zero harmonic suppression.

The Western Radio BN-1 (or BA-80-40 later model) was inferior to the MM but at least had a better output circuit, a link.

Date: 2016-06-26 01:08:39 UTC
From: Leonard Meek
Topic: 26700 Message: 26707

Hue, the tubes I just tested (433 & 447) were probably hearing aid tubes. Those were the only markings on them. I thought they may have been Japanese since they look like the tubes in a Japanese hearing aid that I used to have. I gave up on the proximity tubes because they didn't seem to be too stable. Maybe I just had a bummer. I would guess that they had good quality tubes for lab testing but the specs may have slipped a bit for the production tubes since they weren't going to have much of a life span. Also, they have been rejects. I guessed at the filament voltage. 1.5V lit them up pretty bright. Many other submini tubes have filaments rated at 1.25V +/- 20%. One proximity fuze schematic I have showed two tube filaments in series. Since the "energizer" was a wet cell, I assuned it was a 2V circuit, putting 1V on each tube. The hearing aid tubes are probably 1.25 +/- 20% since they most likely worked off dry batterues. I thought the Rp was fairly high for triodes, but then these are pretty old tubes and the Gm is fairly low. Anyway, fun is still happening.

Leonard

If you’re building from scratch, one way to beat the carbon mic expense is to use a grounded base or gg tube amplifier with the carbon mic in the emitter/ or cathode to

ground. That does mean one triode section or one transistor. Someone on the milsurplus list recently posted a simple circuit for a carbon mic booster. Some of the

military carbon mics were intended for close-talking and are very insensitive.

About 10 years ago i was given a pallet load of 1950s VHF aircraft radios. I took the tubes and transformers out and gave most of those parts away – big expense

of time, but i didn’t want to just metal-recycle them. This talk about carbon mics reminds me i need to inventory what i have left and get rid of most of it. (The

radios were without any control boxes and had no collector value at all.) I am never going to build an AM transmitter from scratch, so i hardly need any of that.

I have used old carbon mic input transformers as audio chokes in low power circuits. In mic service the secondary is rated around 300,000 ohm impedance, so

there’s a lot of turns of wire. However the wire is very thin, probably #38, so it’s only for low currents, and maybe should even be fused if used in a B+ circuit.

I have also thought about using them reversed in crystal set radios, to drop the detector Hi-impedance circuit down to 600 or 300 ohm mag headphones.

Good Sunday amigos !
What a thrill to see something posted about
carbon microphones !!!
My very first AM rig, built with expert guidance
of my mentor CM2DK Ignacio, used a carbon
microphone removed from a local phone,¨donated
by the friendly telephone company repairman¨
BTW, ¨friendly phone company repairman no
longer exist even in Antartica for the local network ¨
Anyway... I used, as prescribed a 6SN7 double
triode, with the first triode grid grounded and the carbon mike
connected to the cathode, but that required a .01 disc ceramic capacitor
to prevent a ¨howl¨ from RF leaking back.
The other half of the 6SN7 fed the 6L6G grid
and the plate of the ¨modulator¨ went to
a 10 Henry choke in a classic Heising modulator.
The RF section was a crystal controlled 6L6G
in version one, improved to a 6AG7 crystal
oscillator driving the 6L6G on the single available quartz crystal 7050
kiloHertz, and this contraption connected to a half wave dipole
with telephone company downlead provided excellent two way AM contacts
all over Cuba,
parts of Mexico and the Antilles...
Of course... you guessed right: this was happening during the peak of
Super Solar Cycle
19....
Good old days to remember amigos !!!

26714. Weskit Bn 1 and United Mitey mite mm3a

Yahoo group: regenrx (2016 — 2017)

From: Kenneth Ketner
Topic: 26714 Message: 26714

You are correct. I had some stuff from both sets on my bench, and got them crossed in my brain. Mm was produced by United surplus materials. Schematic is marked May 1948. Usm must have been physically big for a while because the schematic shows their address in Chicago as 3313-19 West Ogden ave. yes the mm tx is a wreck, lousy output to antenna, no suppression of harmonics, just a wire. I haven't attempted to light the tx, however rx shows signs of possibly working a bit... Presently there remains some undetected flaw or ornery little piece of out of place crud.

I have some paperwork on the Weskit bn1 from the web, but no Bn 1. I hope to build a clone.

Actually, I am hoping for info or leads on either, but more so in support of lashing up a scratch built bn1.

Many thanks.... I really enjoy this regen group

26715. RE: [regenrx] TRF to REGEN

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-26 18:22:57 UTC
From: Hubert Miller
Topic: 26646 Message: 26715

I don’t know if anyone answered this or not. The thinking with the TRFs was to give the average non-technical, non-knob tweaker a simple

reliable radio that didn’t require real careful control adjustments like a regen. Part of the evolution toward giving the non-technically interested

a radio with just tuning and volume controls. The tubes used in early radios, triodes, were prone to self oscillation, so circuits were developed

to cancel that.

-Hue

Has anyone put any effort serious or otherwise with making a conversion like this? I've got several Ideas on doing it but want hopefully some comments if anyone wants. After all the big intent of those designs was NOT to make the amplifiers interact with each other. Close to a regen but no cigar. Wonder what the thinking was?

Re the recent posts on the V-T fuze and the special tubes, here's an article from Radio-Craft magazine, Dec. 1945 -

http://www.americanradiohistory.com/Archive-Radio-Craft/1940s/Radio-Craft-1945-12.pdf

pages 18, 20, 60, 61 of 82 page PDF.

It says 130 million of the tubes were made!! Where did they all go? You'd think a lot were left over. Maybe not.

Hue,

Most probably ended up having "Deadly Encounters of the worst kind" with
enemy Zeros and ships. Perhaps Uncle Sam destroyed any excess as
possibly leaking sensitive information. . .

HF/LF RADIOS:
Grundigs: S-350 (~2006), G6 (2011) & S450DLX (2014).
HOMEBREW: 7 Tube+Rect 1v3 Regenerative RX for LF (built 2015)
Icom: IC-735 Transceiver (~1990).
Icom: R-75, Cascaded 250/125Hz CW-Filt, Panadapter. (~2009)
Icom: IC-7200 Transceiver (~2015).
R-Shack: DX-380 digital portable (~1990).
SDR: Softrock Ensemble II LF (built from a kit 2015).
Zenith: Royal-7000 Transoceanic Portable (~1968).

ACC: HOMEBREW LF-MF Pre-Amp, MFJ-993B HF Auto-Tuner.
HOMEBREW 4 Port Multicoupler, Feeds Antenna to 4 RX's.
HOMEBREW 8 Hz Audio Filter.
Timewave DSP-599zx Audio Filter.
Behringer 1202fx Audio Mixer (for mixing/routing audio).

ANTENNAS: 88 foot Long Ladder-line fed dipole, 35 feet AGL for MW/SW.
Active Mini-Whip, 36 Feet AGL for LF/MW/SW.
37 foot "Low Noise Vertical", 11 feet AGL for LF/MW/SW.

Merced, Central California, 37, 18, 37N 120, 30, 6W CM97rh

Hue, I have that Radio Craft issue on my computer. It's a little different from OP1480, which came out in May 1946. According to the OP, the VT didn't stand for anythinf. It was just an ID for shipping purposes. I skimmed Radio Craft the article but still didn't see any mention of voltages. The one radio I built with the PF tubes worked fine at first , but now not so much. My battery voltages are still good, so I assume the tubes are failing. Of course I know what "assume" breaks down to. I'm trying another circuit now but it's not going too well. My eye sight is declining, and my XYL has a growing list of "honey do" projects for me.

Leonard
